ADDITIVE GROUP THEORY AND NON-UNIQUE FACTORIZATIONS

ALFRED GEROLDINGER

1. Introduction

This article is the extended and revised version of notes written for the Advanced Course in Combinatorics and Geometry: Additive Combinatorics. The course took place at the Centre de Recerca Matemàtica (CRM) at Barcelona in spring 2008. It gives a survey on the interaction between two, at first glance very disparate areas of mathematics: Non-Unique Factorization Theory (see [71, 70, 13, 88, 124]) and Additive Group Theory (see [103, 36, 104, 107, 23, 130, 51]). The main objective of factorization theory is a systematic treatment of phenomena related to the non-uniqueness of factorizations in monoids and integral domains. In the setting of Krull monoids (the main examples we have in mind are the multiplicative monoids of rings of integers of algebraic number fields) most problems can be translated into zero-sum problems over the class group. It will be a main aim of this course to highlight this relationship.

In Section 3 we introduce the basic concepts of factorization theory, point out that arithmetical questions in arbitrary Krull monoids can be translated into combinatorial questions on zero-sum sequences over the class group and formulate some main problems (Section 3.D). In Section 4 we study the Davenport constant, and using group algebras we derive its precise value for $p$-groups (Theorem 4.10). In Section 5 we discuss the structure of sets of lengths (see Theorems 5.3, 5.9, 5.10 and 5.11). The characterization problem (Section 5.C) is a central topic. We give a proof in the case of cyclic groups and elementary 2-groups (Corollary 7.28), and this proof requires most of the results from additive group theory discussed in the previous parts. Section 6 starts with addition theorems, and then the Erdős-Ginzburg-Ziv constant and some of its variants are studied. We outline the power of the inductive method and determine the Davenport and the Erdős-Ginzburg-Ziv constant for groups of rank at most two (Theorem 6.13). Section 7 deals with inverse zero-sum problems. The focus is on cyclic groups and on groups of rank two.

2. Notations

Our notation and terminology is consistent with [71]. We briefly gather some key notions. We denote by $\mathbb{N}$ the set of positive integers, and we put $\mathbb{N}_0 = \mathbb{N} \cup \{0\}$. For real numbers $a, b \in \mathbb{R}$ we set $[a, b] = \{x \in \mathbb{R} | a \leq x \leq b\}$, and we define $\sup \emptyset = \max \emptyset = \min \emptyset = 0$.

Let $A, B \subset \mathbb{Z}$ be finite nonempty subsets. Then $A + B = \{a + b | a \in A, b \in B\}$ is their sumset. We denote by $\Delta(A)$ the set of (successive) distances of $A$, that is if $A = \{a_1, \ldots, a_t\}$ with $t \in \mathbb{N}$ and $a_1 < \ldots < a_t$, then $\Delta(A) = \{a_{v+1} - a_v | v \in [1, t-1]\}$). Moreover, we set $\Delta(\emptyset) = \emptyset$. A subset $P \subset \mathbb{Z}$ is called an arithmetical progression with difference $d \in \mathbb{N}$ if $P$ is finite nonempty and $\Delta(P) \subset \{d\}$.

If $A \subset \mathbb{N}$, we call

$$\rho(A) = \frac{\max A}{\min A} \in \mathbb{Q}_{\geq 1}$$

the elasticity of $A$, and we set $\rho(\{0\}) = 1$.

2000 Mathematics Subject Classification. 11P70, 11B50, 11B75, 13F05, 13A05, 20M14.

Key words and phrases. non-unique factorizations, Krull monoids, zero-sum problems.
By a *monoid* we always mean a commutative semigroup with identity which satisfies the cancellation law (that is, if $a, b, c$ are elements of the monoid with $ab = ac$, then $b = c$ follows). If $R$ is an integral domain and $R^* = R \setminus \{0\}$ its multiplicative semigroup of non-zero elements, then $R^*$ is a monoid.

Throughout this paper, let $H$ be a multiplicative monoid and $G$ an additive finite abelian group.

3. Basic concepts of non-unique factorizations

We denote by $H^\times$ the set of invertible elements of $H$, and we say that $H$ is *reduced* if $H^\times = \{1\}$. Let $H_{\text{red}} = H/H^\times = \{aH^\times \mid a \in H\}$ be the associated reduced monoid, and $\mathbb{q}(H)$ a quotient group of $H$.

Let $a, b \in H$. We say that $a$ divides $b$ (and we write $a \mid b$) if there is an element $c \in H$ such that $b = ac$. We say that $a$ and $b$ are *associated* (and we write $a \simeq b$) if $a \mid b$ and $b \mid a$ (equivalently, $aH^\times = bH^\times$).

A monoid $F$ is called *free* (abelian, with basis $P \subset F$) if every $a \in F$ has a unique representation in the form

$$a = \prod_{p \in P} p^{v_p(a)} \text{ with } v_p(a) \in \mathbb{N}_0 \text{ and } v_p(a) = 0 \text{ for almost all } p \in P.$$  

In this case, $F$ is (up to canonical isomorphism) uniquely determined by $P$, and conversely $P$ is uniquely determined by $F$.

We set $F = \mathcal{F}(P)$ and call

$$|a|_F = |a| = \sum_{p \in P} v_p(a) \text{ the length of } a.$$

An element $a \in H$ is called

- an *atom* (or an irreducible element) if $a \notin H^\times$ and, for all $b, c \in H$, $a = bc$ implies $b \in H^\times$ or $c \in H^\times$. We denote by $\mathcal{A}(H)$ the set of all atoms of $H$.
- a *prime* (or a prime element) if $a \notin H^\times$ and, for all $b, c \in H$, $a = bc$ implies $a \mid b$ or $a \mid c$.

The monoid $H$ is called

- *atomic* if every $a \in H \setminus H^\times$ is a product of atoms.
- *factorial* if it satisfies one of the following equivalent conditions:
  
  (a) Every $a \in H \setminus H^\times$ is a product of primes.
  (b) $H$ is atomic, and every atom is a prime.
  (c) Every $a \in H \setminus H^\times$ is a product of atoms, and this factorization is unique up to associates and the order of the factors.
  (d) $H_{\text{red}}$ is free (in that case $H_{\text{red}}$ is free with basis $\{pH^\times \mid p \in P\}$ where $P$ denotes the set of primes of $H$).
  (e) $H = H^\times \times \mathcal{F}(P)$ for some subset $P \subset H$ (in that case $P$ is a maximal set of pairwise non-associated primes of $H$).

Every prime is an atom, and every factorial monoid is atomic. An element $a \in H$ is an atom [a prime] of $H$ if and only if $aH^\times$ is an atom [a prime] of $H_{\text{red}}$. Thus $H_{\text{red}}$ is atomic [factorial] if and only if $H$ has this property.

By a *factorization* $z$ of an element $a \in H$ we mean an equation of the form

$$z : a = u_1 \cdots u_l \text{ with } l \in \mathbb{N}_0 \text{ and } u_1, \ldots, u_l \text{ are atoms}.$$

The number of atoms $l$ is called the length of the factorization, and two factorizations which differ only in the order of their factors and up to associates are considered as being equal. This concept can be formalized as follows.
The free monoid $Z(H) = \mathcal{F}(\mathcal{A}(H_{\text{red}}))$, whose basis is the set of atoms in $H_{\text{red}}$, is called the \textit{factorization monoid} of $H$. The homomorphism
\[ \pi_H = \pi: Z(H) \to H_{\text{red}}, \text{ defined by } \pi(z) = \prod_{u \in \mathcal{A}(H_{\text{red}})} u^{|u|_H(z)}, \]
is called the \textit{factorization homomorphism} of $H$. For $a \in H$, we set
\[ Z_H(a) = Z(a) = \pi^{-1}(aH^\times) \subseteq Z(H), \]
and we call the elements $z \in Z(a)$ the \textit{factorizations} of $a$. We say that $a$ has \textit{unique factorization} if $|Z(a)| = 1$. For a factorization $z \in Z(a)$, we call $|z|$ the \textit{length} of $z$ (clearly, this coincides with the above informal definition), and the set
\[ L_H(a) = L(a) = \{ |z| \mid z \in Z(a) \} \subseteq \mathbb{N} \]
is called the \textit{set of lengths} of $a$.

Note that $0 \in L(a)$ if and only if $a \in H^\times$ and then $L(a) = \{0\}$. We have $1 \in L(a)$ if and only if $a$ is an atom and then $L(a) = \{1\}$. The monoid $H$ is atomic if and only if $Z(a) \neq \emptyset$ for all $a \in H$, and it is factorial if and only if $|Z(a)| = 1$ for all $a \in H$. For every $b \in H$, we have
\[ Z(a)Z(b) \subseteq Z(ab) \quad \text{and} \quad L(a) + L(b) \subseteq L(ab). \]

Furthermore, the monoid $H$ is called
- \textit{half-factorial} if $|L(a)| = 1$ for all $a \in H$.
- \textit{an FF-monoid} (a finite factorization monoid) if $Z(a)$ is finite and nonempty for all $a \in H$.
- \textit{a BF-monoid} (a bounded factorization monoid) if $L(a)$ is finite and nonempty for all $a \in H$.

Half-factorial monoids and domains have received a lot of attention in the literature (see [14], [20], [123] for recent surveys). Here is a first, very simple but important observation.

**Lemma 3.1.** Let $H$ be atomic but not half-factorial. Then for every $N \in \mathbb{N}$ there exists some $a \in H$ such that $|L(a)| \geq N + 1$.

**Proof.** If $a = u_1 \cdots u_k = v_1 \cdots v_l$ with $k < l$ and $u_1, \ldots, u_k, v_1, \ldots, v_l \in \mathcal{A}(H)$, then
\[ c = a^N = (u_1 \cdots u_k)^\nu (v_1 \cdots v_l)^{N-\nu} \quad \text{for all } \nu \in [0, N] \]
whence $\{ \nu k + l(N - \nu) : \nu \in [0, N] \} \subseteq L(c)$. \qed

### 3.3 Arithmetical invariants

Most monoids studied so far in factorization theory are BF-monoids. In particular the multiplicative monoids of noetherian domains are BF-monoids ([71, Theorem 2.2.9]). We call
\[ \mathcal{L}(H) = \{ L(a) \mid a \in H \} \]
the \textit{system of sets of lengths} of $H$. If $H$ is a BF-monoid, then $\mathcal{L}(H)$ is a set of finite nonempty subsets of the non-negative integers, and apart from the trivial case of half-factoriality, for every $N \in \mathbb{N}$ there is an $L \in \mathcal{L}(H)$ such that $|L| > N$. In order to describe the structure of sets of lengths we introduce the following arithmetical invariants.

**Definition 3.2.** Let $H$ be a BF-monoid.

1. For $a \in H$, we call $\rho(a) = \rho(L(a))$ the \textit{elasticity} of $a$ and
\[ \rho(H) = \sup\{ \rho(a) \mid a \in H \} = \sup\{ \rho(L) \mid L \in \mathcal{L}(H) \} \in \mathbb{R}_{\geq 1} \cup \{\infty\} \]
the \textit{elasticity} of $H$. 

2. Let \( k \in \mathbb{N} \). If \( H = H^\times \), we set \( \rho_k(H) = \lambda_k(H) = k \), and if \( H \neq H^\times \), then we define
\[
\rho_k(H) = \sup\{\max L \mid L \in \mathcal{L}(H), \ k \in L\} \in \mathbb{N} \cup \{\infty\} \quad \text{and} \quad 
\lambda_k(H) = \min\{\min L \mid L \in \mathcal{L}(H), \ k \in L\} \in [1, k].
\]

3. We call
\[
\Delta(H) = \bigcup_{L \in \mathcal{L}(H)} \Delta(L) \subset \mathbb{N}
\]
the set of distances of \( H \).

Clearly, \( H \) is half-factorial if and only if \( \Delta(H) = \emptyset \) if and only if \( \rho_k(H) = k \) for all \( k \in \mathbb{N} \). Furthermore, \( \mid \Delta(H) \mid = 1 \) if and only if all sets of lengths are arithmetical progressions with the same difference. Whereas the elasticity may be infinite in non-principal orders of algebraic number fields ([71, Corollary 3.7.2]), we shall prove that it is finite in all Krull monoids with finite class group (thus in particular in all principal orders; see Theorems 3.17 and 4.11).

**Lemma 3.3.** If \( H \) is a BF-monoid and \( \Delta(H) \) is nonempty, then \( \min \Delta(H) = \gcd \Delta(H) \).

**Proof.** We set \( d = \gcd \Delta(H) \). Clearly, it suffices to show that \( d \in \Delta(H) \). There are \( t \in \mathbb{N}, d_1, \ldots, d_t \in \Delta(H) \) and \( m_1, \ldots, m_t \in \mathbb{Z} \setminus \{0\} \) such that \( d = m_1d_1 + \ldots + m_td_t \). After renumbering if necessary there is some \( s \in [1, t] \) such that \( m_1, \ldots, m_s, -m_{s+1}, \ldots, -m_t \) are positive. For every \( i \in [1, t] \), there are \( x_i \in \mathbb{N} \) and \( a_i \in H \) such that
\[
\{x_i, x_i + d_i\} \subset L(a_i) \quad \text{for every} \quad i \in [1, s]
\]
and
\[
\{x_i - d_i, x_i\} \subset L(a_i) \quad \text{for every} \quad i \in [s+1, t].
\]
Then we get
\[
\begin{align*}
\{k & = \sum_{i=1}^{s} m_i x_i - \sum_{i=s+1}^{t} m_i x_i, \ t = \sum_{i=1}^{s} m_i (x_i + d_i) - \sum_{i=s+1}^{t} m_i (x_i - d_i) \} \\
& \subset \sum_{i=1}^{s} \{m_i x_i, \ m_i (x_i + d_i)\} - \sum_{i=s+1}^{t} \{m_i (x_i - d_i), m_i x_i\} \\
& \subset L(a_1^{m_1}, \ldots, a_t^{m_1}) \subset L.
\end{align*}
\]
Since \( d \leq \min \Delta(H) \), it follows that \( d = t-k \) is a successive distance of \( L \) and hence \( d \in \Delta(L) \subset \Delta(H) \). \( \square \)

The structure of sets of lengths will be studied in detail in Section 5. We continue with concepts which consider factorizations in a more direct way and not only their lengths.

**Definition 3.4.** Let \( H \) be atomic and \( z, z' \in \mathbb{Z}(H) \), say
\[
z = u_1 \cdot \ldots \cdot u_l v_1 \cdot \ldots \cdot v_m \quad \text{and} \quad z' = u_1 \cdot \ldots \cdot u_l w_1 \cdot \ldots \cdot w_n,
\]
where \( l, m, n \in \mathbb{N}_0 \), \( u_1, \ldots, u_l, v_1, \ldots, v_m, w_1, \ldots, w_n \in A(H_{\text{red}}) \) and
\[
\{v_1, \ldots, v_m\} \cap \{w_1, \ldots, w_n\} = \emptyset.
\]
Then we call \( d(z, z') = \max\{m, n\} \in \mathbb{N}_0 \) the distance between \( z \) and \( z' \).

The distance function \( d : \mathbb{Z}(H) \times \mathbb{Z}(H) \to \mathbb{N}_0 \) is a metric. The following observation is analogue to Lemma 3.1.

**Lemma 3.5.** Let \( H \) be atomic but not factorial. Then for every \( N \in \mathbb{N} \) there exists some \( a \in H \) such that \( |\mathbb{Z}(a)| \geq N + 1 \), and there exist factorizations \( z, z' \in \mathbb{Z}(a) \) such that \( d(z, z') \geq 2N \).
This phenomenon motivates the following definition.

**Definition 3.6.** Let $H$ be atomic.

1. We define the *catenary degree* $c(a)$ for $a \in H$ to be the smallest $N \in \mathbb{N}_0 \cup \{\infty\}$ such that, for any two factorizations $z, z'$ of $a$, there exists a finite sequence $z = z_0, z_1, \ldots, z_k = z'$ of factorizations of $a$ satisfying that $d(z_{i-1}, z_i) \leq N$ for all $i \in [1, k]$.

2. Globally, we define $c(H) = \sup \{c(a) \mid a \in H\} \in \mathbb{N}_0 \cup \{\infty\}$, and we call $c(H)$ the *catenary degree* of $H$.

The next lemma gathers some elementary properties. In particular, Lemma 3.7.1 shows that $H$ is factorial if and only if the catenary degree $c(H) = 0$.

**Lemma 3.7.** Let $H$ be atomic and $a \in H$.

1. $c(a) \leq \sup L(a)$, and $c(a) = 0$ if and only if $|Z(a)| = 1$.

2. Let $z, z' \in Z(a)$ and $z \neq z'$, then $2 + ||z| - |z'|| \leq d(z, z')$.

3. If $|Z(a)| \geq 2$, then $2 + \sup \Delta(L(a)) \leq c(a)$. In particular, $2 + \sup \Delta(H) \leq c(H)$.

4. If $c(a) \leq 2$, then $|L(a)| = 1$, and if $c(a) \\leq 3$, then $L(a)$ is an arithmetical progression with difference $1$.

**Proof.** 1. If $z, z' \in Z(a)$, then $d(z, z') \leq \max\{|z|, |z'|\} \leq \sup L(a)$. Hence $c(a) \leq \sup L(a)$. The second assertion follows by the very definition of $c(a)$.

2. Let $z, z' \in Z(a)$ be distinct, $x = \gcd(z, z')$, and $z = xy, z' = xy'$, where $y, y' \in Z(H)$. Then $|y| \geq 2, |y'| \geq 2$ and $d(z, z') = \max\{|y|, |y'|\}$. Thus it follows that $2 + ||z| - |z'|| = 2 + |y| - |y'| \leq \max\{|y|, |y'|\} = d(z, z')$.

3. We may assume that $\Delta(L(a)) \neq \emptyset$, and we must prove that $2 + s \leq c(a)$ for every $s \in \Delta(L(a))$. If $s \in \Delta(L(a))$, then there exist factorizations $z, z' \in Z(a)$ such that $|z'| = |z| + s$, and there is no factorization $z'' \in Z(a)$ with $|z| < |z''| < |z'|$. By definition of $c(a)$, there exist factorizations $z = z_0, z_1, \ldots, z_k = z' \in Z(a)$ such that $d(z_{i-1}, z_i) \leq c(a)$ for all $i \in [1, k]$. Thus there exists some $i \in [1, k]$ such that $|z_{i-1}| \leq |z|$ and $|z_i| \geq |z'|$. Hence $2 + s \leq 2 + |z_i| - |z_{i-1}| \leq d(z_{i-1}, z_i) \leq c(a)$.

4. Obvious by 3. \qed

Next we consider local tameness. We start with the formal definition, and then we discuss the meaning of this concept in some detail.

**Definition 3.8.** Suppose that $H$ is atomic.

1. For $a, b \in H$ let $\omega(a, b)$ denote the smallest $N \in \mathbb{N}_0 \cup \{\infty\}$ with the following property:

   For all $n \in \mathbb{N}$ and $a_1, \ldots, a_n \in H$, if $a = a_1 \cdots a_n$ and $b \mid a$, then there exists a subset $\Omega \subseteq [1, n]$ such that $|\Omega| \leq N$ and $b \mid \prod_{\nu \in \Omega} a_{\nu}$.

   In particular, if $b \nmid a$, then $\omega(a, b) = 0$. For $b \in H$ we define

   $\omega(H, b) = \sup \{\omega(a, b) \mid a \in H\} \in \mathbb{N}_0 \cup \{\infty\}$.

2. For $a \in H$ and $x \in Z(H)$ let $t(a, x) \in \mathbb{N}_0 \cup \{\infty\}$ denote the smallest $N \in \mathbb{N}_0 \cup \{\infty\}$ with the following property:

   If $Z(a) \cap xZ(H) \neq \emptyset$ and $z \in Z(a)$, then there exists $z' \in Z(a) \cap xZ(H)$ such that $d(z, z') \leq N$. 
For subsets $H' \subset H$ and $X \subset \mathcal{Z}(H)$, we define
\[
t(H', X) = \sup \{ t(a, x) \mid a \in H', x \in X \} \in \mathbb{N}_0 \cup \{ \infty \}.
\]

$H$ is called \textit{locally tame} if $t(H, u) < \infty$ for all $u \in \mathcal{A}(\text{H}_{\text{red}})$.

Local tameness is a basic finiteness property in the theory of non-unique factorizations, in the sense that in many situations where the finiteness of an arithmetical invariant such as the catenary degree or the set of distances is studied, local tameness has to be proved first (see also the sketch of the proof of Theorem 5.9). The closely related $\omega(H, \cdot)$-invariants, introduced in [68], are further well-established invariants in the theory of non-unique factorizations, which appear also in the context of direct-sum decompositions of modules [26, Remark 1.6].

For simplicity of notation suppose that $H$ is atomic and reduced, and let $u \in \mathcal{A}(H)$. Then $u$ is a prime if and only if $\omega(H, u) = 1$. Thus $\omega(H, u)$ measures how far away is $u$ from being a prime. Let $a \in H$. If $a \nmid a$, then $t(a, u) = 0$ by definition. Suppose that $a \mid a$. Then $t(a, u)$ is the smallest $N \in \mathbb{N}_0 \cup \{ \infty \}$ with the following property: if $z = a_1 \ldots a_n$ is any factorization of $a$ where $a_1, \ldots, a_n$ are atoms, then there exist a subset $\Omega \subset [1, n]$, say $\Omega = [1, k]$, and a factorization $z' = u_{a_1} \ldots u_{a_{k-1}} \ldots a_n \in \mathcal{Z}(a)$, with atoms $u_2, \ldots, u_k$, such that $\max \{ k, l \} \leq N$. Thus $t(a, u)$ measures how far away from any given factorization $z$ of $a$ there is a factorization $z'$ of $a$ which contains $u$, and if $u$ is not a prime then $\omega(H, u) \leq t(H, u)$. Suppose that $u$ is a prime. Then every factorization of $a$ contains $u$, we can choose $z' = z$ in the above definition, obtain that $d(z, z') = d(z, z) = 0$ and hence $t(H, u) = 0$. Whereas in monoids, which satisfy the ascending chain condition for $\mathfrak{a}$-ideals, we have $\omega(H, u) < \infty$ for all atoms $u \in \mathcal{A}(H)$, this does not hold for the $t(H, u)$ values (see [74, Theorems 3.6 and 4.4]).

### 3B Krull monoids

Krull monoids play a central role in factorization theory. We briefly summarize some of their main properties without giving any proofs. Then we discuss two main examples of Krull monoids: those stemming from domains and the monoid of zero-sum sequences over an abelian group. For more on the theory of Krull monoids we refer to the monographs [87, 79, 71]. A detailed discussion of further examples may be found in [71, Examples 2.3.2 and 7.4.2].

**Definition 3.9.** (Krull monoids and class groups)

1. Let $D$ be a monoid and $H \subset D$ a submonoid with $q(H) \subset q(D)$.
   a. Then $H \subset D$ is called \textit{saturated} if $q(H) \cap D = H$ (that is, if $a, b \in H$ and $a \mid b$ in $D$, then $a \mid b$ in $H$).
   b. For $a \in q(D)$ we denote by $[a] = [a]_{D/H} = aq(H) \in q(D)/q(H)$ the class containing $a$.
      We call $D/H = \{ [a] \mid a \in D \} \subset q(D)/q(H)$ the \textit{class group} of $D$ modulo $H$.

2. $H$ is called a \textit{Krull monoid} if $H_{\text{red}}$ is a saturated submonoid of a free monoid.

3. Let $H$ be a Krull monoid and suppose that $H_{\text{red}} \subset D = \mathcal{F}(P)$ is a saturated submonoid of a free monoid such that every $p \in P$ is the greatest common divisor of finitely many elements of $H_{\text{red}}$. Then we call $D$ a monoid of \textit{divisors} and $P$ a set of \textit{prime divisors} of $H$ (for short, we refer to them as primes).

Let $H \subset D$ be as above. If $q(D)/q(H)$ is finite (this condition is fulfilled throughout the present article), then $D/H = q(D)/q(H)$. Class groups will be written additively whence $[1]$ is the zero element of $D/H$. Moreover, $H \subset D$ is saturated if and only if
\[
H = \{ a \in D \mid [a] = [1] \}.
\]
Every Krull monoid possesses a monoid of divisors, and if $D$ and $D'$ are monoids of divisors of $H$, then there is a unique isomorphism $\Phi: D \rightarrow D'$ with $\Phi|_{H\text{red}} = \text{id}$. Hence the class group
$$\mathcal{C}(H) = D/H\text{red}$$
and the subset $\{[p] \in \mathcal{C}(H) \mid p \in P\}$
of all classes containing primes are uniquely determined by $H$ (up to canonical isomorphism) and hence $\mathcal{C}(H)$ will be called the class group of the Krull monoid $H$.

Now we consider domains and outline when the multiplicative monoid of a domain is a Krull monoid (more details and proofs can be found in [71, Section 2.10]). Let $R$ be a domain,
$$\mathcal{H}(R) = \{aR \mid a \in R^*\}$$
the monoid of non-zero principal ideals and
$$\mathcal{I}^*(R) = \{I \triangleleft R \mid I \text{ is invertible}\}$$
the monoid of invertible ideals (recall, that a non-zero ideal $I$ of $R$ is invertible if there is a non-zero ideal $J$ of $R$ such that their product $IJ$ is a principal ideal). Then $(R^*)_{\text{red}} = \mathcal{H}(R)$, the prime elements of the monoid $\mathcal{I}^*(R)$ are precisely the non-zero prime ideals of $R$, and $\mathcal{H}(R) \subset \mathcal{I}^*(R)$ is saturated.

**Theorem 3.10.** Let $R$ be an integral domain.

1. The following statements are equivalent:
   (a) $R^*$ is a Krull monoid.
   (b) $R$ is completely integrally closed and satisfies the ascending chain condition for $v$-ideals (also called divisorial ideals).
   (c) $R$ satisfies the ascending chain condition for $v$-ideals and $R_m$ is a discrete valuation domain for all $v$-maximal $v$-ideals of $R$.

2. The following statements are equivalent:
   (a) $R$ is integrally closed, noetherian and every non-zero prime ideal of $R$ is maximal.
   (b) $R$ is a one-dimensional Krull domain.
   (c) Every non-zero ideal is a product of prime ideals.

A domain $R$ is called a **Krull domain** if it satisfies the equivalent conditions of Theorem 3.10.1. In particular, every integrally closed noetherian domain is a Krull domain.

A domain $R$ is called a **Dedekind domain** if it satisfies the equivalent conditions of Theorem 3.10.2. Suppose $R$ is a Dedekind domain. Then $\mathcal{I}^*(R)$ is a monoid of divisors of $\mathcal{H}(R)$, the set of non-zero prime ideals is a set of prime divisors of $\mathcal{H}(R)$, and the class group of $\mathcal{H}(R) \subset \mathcal{I}^*(R)$ is the usual ideal class group of $R$. If $K$ is an algebraic number field and $\mathfrak{o}_K$ the ring of integers of $K$, then $\mathfrak{o}_K$ is a Dedekind domain with finite class group and every class contains infinitely many primes.

Next we discuss the monoid of zero-sum sequences over an abelian group, which will turn out to be a Krull monoid. It connects the theory of non-unique factorizations with additive group theory and combinatorial number theory.

**Definition 3.11.** Let $G_0 \subset G$ be a subset.

1. Let $\mathcal{F}(G_0)$ be the free (multiplicative) monoid with basis $G_0$. The elements of $\mathcal{F}(G_0)$ are called sequences over $G_0$. We write sequences $S \in \mathcal{F}(G_0)$ in the form
$$S = \prod_{g \in G_0} g^{v_g(S)} = g_1 \cdot \ldots \cdot g_l \in \mathcal{F}(G_0),$$
where $v_g(S) \in \mathbb{N}_0$. 

2. If $S$ is as above, then
\[
\sigma(S) = \sum_{i=1}^{t} g_i = \sum_{g \in G} \nu_g(S) g \in G \quad \text{is called the sum of } S,
\]
and we denote by $B(G_0) = \{ S \in F(G_0) \mid \sigma(S) = 0 \}$ the monoid of zero-sum sequences (block monoid) over $G_0$. The elements of $B(G_0)$ are called zero-sum sequences, and the atoms of $B(G_0)$ are called minimal zero-sum sequences.

For every arithmetical invariant $s(H)$ defined for the monoid $H$, we write $s(G_0)$ instead of $s(B(G_0))$ whenever the precise meaning is clear from the context. For example, we set $\mathbb{A}(G_0) = \mathbb{A}(B(G_0))$, $\mathbb{L}(G_0) = \mathbb{L}(B(G_0))$, $\Delta(G_0) = \Delta(B(G_0))$ and so on.

**Proposition 3.12.** Let $G_0 \subset G$ be a nonempty subset.
1. $B(G_0) \subset F(G_0)$ is saturated and thus $B(G_0)$ is a Krull monoid.
2. $\mathbb{A}(G_0)$ is finite and thus $B(G_0)$ is finitely generated.
3. If $|G| \neq 2$, then $F(G)$ is a monoid of divisors for $B(G)$, $\mathbb{L}(B(G)) \cong G$, and every class of $B(G)$ contains exactly one prime.
4. The following statements are equivalent:
   (a) $|G| \leq 2$.
   (b) $B(G)$ is factorial.
   (c) $B(G)$ is half-factorial.

**Proof.**
1. This follows immediately from the definitions.
2. Every atom of $B(G_0)$ divides the zero-sum sequence
\[
B = \prod_{g \in G_0} g^{\nu_g(g)}
\]
and hence there are only finitely many atoms.
3. Let $|G| \neq 2$. To verify that $F(G)$ is a monoid of divisors for $B(G)$, let $g \in G$ be given. If $\nu_g(g) \geq 3$, then $g = \gcd(g^3, g(-g))$. If $\nu_g(g) = 2$, then there is an atom $h \in G \setminus \{0, g\}$ and $g = \gcd(g^2, gh(g-h))$.

The map $\sigma: F(G) \to G$ is a monoid epimorphism. If $S, S' \in F(G)$, then $\sigma(S) = \sigma(S')$ if and only if $S' \in [S] = \text{Sq}(B(G))$. Thus $\sigma$ induces a group isomorphism $\Phi: F(G)/B(G) \to G$, defined by $\Phi([S]) = \sigma(S)$, and we have $[S] \cap G = \{g\}$. Thus the class $[S]$ contains exactly one prime.
4. (a) $\Rightarrow$ (b) If $G = \{0\}$, then $B(G) = F(G) \cong (\mathbb{N}_0, +)$ is factorial. Suppose that $G = \{0, e\}$. Then $\mathbb{A}(G) = \{0, e^2\}$, every atom is a prime and hence $B(G)$ is factorial (indeed, $B(G) \cong (\mathbb{N}_0^2, +)$).
   (b) $\Rightarrow$ (c) Obvious.
   (c) $\Rightarrow$ (a) Suppose there is some $g \in G$ with $\nu_g(g) \geq 3$. Then $U = g^n, -U = (-g)^n, V = (-g)g$ are atoms of $B(G)$ and $-U \cdot U = V^n$, a contradiction to half-factoriality. Thus $\nu_g(g) \leq 2$ for all $g \in G$.

Assume to the contrary, that there are two distinct non-zero elements $e_1, e_2 \in G$ and set $e_0 = e_1 + e_2$. Then $U = e_0 \epsilon_{1,2}$ and $V_i = e_i^2$ are atoms of $B(G)$ for $i \in \{0, 2\}$. But $U^2 = V_0 V_1 V_2$ is again a contradiction to half-factoriality. Thus $G$ has no elements of order greater than or equal to 3, and at most one element of order 2 which implies $|G| \leq 2$.

\[ \square \]

### 3.C Transfer principles

A central method in factorization theory is to study the arithmetic in auxiliary monoids and to shift the results to monoids and domains of arithmetical interest. We start with the crucial definition.
Definition 3.13. A monoid homomorphism $\theta: H \to B$ is called a transfer homomorphism if it has the following properties:

1. $B = \theta(H)B^\times$ and $\theta^{-1}(B^\times) = H^\times$.
2. If $u \in H$, $b, c \in B$ and $\theta(u) = bc$, then there exist $v, w \in H$ such that $u = vw$, $\theta(v) \simeq b$ and $\theta(w) \simeq c$.

Thus the strategy is to find, for a given monoid $H$, a simpler monoid $B$, to study the arithmetic in $B$, and then to shift the arithmetical results from $B$ back to $H$. The next proposition shows that if a shift back is possible.

Proposition 3.14. Let $\theta: H \to B$ be a transfer homomorphism of atomic monoids and $u \in H$.

1. If $n \in \mathbb{N}$, $b_1, \ldots, b_n \in B$ and $\theta(u) \simeq b_1 \cdots b_n$, then there exist $u_1, \ldots, u_n \in H$ such that $u \simeq u_1 \cdots u_n$ and $\theta(u_v) \simeq b_v$ for all $v \in [1, n]$.
2. $u$ is an atom of $H$ if and only if $\theta(u)$ is an atom of $B$.
3. $L_H(u) = L_B(\theta(u))$.
4. $\mathcal{L}(H) = \mathcal{L}(B)$. In particular, $H$ is a BF-monoid if and only if $B$ is a BF-monoid, and then we have $\rho(H) = \rho(B)$ and $\Delta(H) = \Delta(B)$.

Proof. We suppose that $H$ and $B$ are reduced.

1. This follows by induction on $n$.
2. If $u \in \mathcal{A}(H)$ and $\theta(u) = bc$ for some $b, c \in B$, then there exist $v, w \in H$ such that $u = vw$, $\theta(v) = b$ and $\theta(w) = c$. Hence $v = 1$ or $w = 1$ and thus $b = 1$ or $c = 1$. If $\theta(u) \in \mathcal{A}(B)$ and $u = vw$ for some $v, w \in H$, then $\theta(u) = \theta(v)\theta(w)$ implies $\theta(v) = 1$ or $\theta(w) = 1$ and thus $v = 1$ or $w = 1$.
3. By (T 1), we have $u = 1$ if and only if $\theta(u) = 1$, and by definition we have $L_H(1) = \{0\} = L_B(\theta(u))$.
4. This follows immediately from 3. \hfill $\Box$

We introduce the Davenport constant which will be investigated in detail in Section 4. Recall that $\mathcal{A}(G_0)$ is finite by Proposition 3.12.

Definition 3.15. Let $G_0 \subseteq G$ be a nonempty subset. Then

$$D(G_0) = \max\{|U| \mid U \subseteq \mathcal{A}(G_0)\} \in \mathbb{N}_0$$

is called the Davenport constant of $G_0$.

The next result gives the required link between factorization theory on the one side and additive group theory and combinatorial number theory on the other side.

Theorem 3.16. Let $H$ be a reduced Krull monoid with finite class group, $H \subseteq D = \mathcal{F}(P)$ a monoid of divisors and $G_0 = \{[p] \mid p \in P\} \subseteq G = D/H$ the set of classes containing primes. Let $\tilde{\beta}: D \to \mathcal{F}(G_0)$ be the unique homomorphism satisfying $\tilde{\beta}(p) = [p]$ for all $p \in P$.

1. For $a \in D$ we have $\tilde{\beta}(a) \in B(G_0)$ if and only if $a \in H$. Thus $\tilde{\beta}(H) = B(G_0)$ and $\tilde{\beta}^{-1}(B(G_0)) = H$. 

2. The restriction $\beta = \tilde{\beta}|H : H \to B(G_0)$ is a transfer homomorphism. In particular, we have $\mathcal{L}(H) = \mathcal{L}(G_0)$.

3. $D(G_0)$ is the maximum of all $l \in \mathbb{N}$ with the following property: There exists an atom $u \in H$ such that $u$ is the product of $l$ primes of $D$.

4. We have $\pi(G_0) \leq \xi(H) \leq \max\{\pi(G_0), 2\}$.

Proof. 1. Let $a = p_1 \cdots p_l \in D$ where $l \in \mathbb{N}$ and $p_1, \ldots, p_l \in P$. Then

$$\tilde{\beta}(a) = [p_1] \cdots [p_l] \in \mathcal{F}(G_0)$$

and $\sigma([p_1] \cdots [p_l]) = [p_1] + \ldots + [p_l] = [a]$.

Since $H \subset D$ is saturated, we have $[a] = 0 \in G$ if and only if $a \in H$, and thus all assertions follow.

2. By 1., $\beta : H \to B(G_0)$ is surjective and $\beta^{-1}(1) = \{1\}$. Let $a = p_1 \cdots p_l \in H$, with $l \in \mathbb{N}$ and $p_1, \ldots, p_l \in P$, and suppose that $\beta(a) = BC$, say $B = [p_1] \cdots [p_k]$ and $C = [p_{k+1}] \cdots [p_l]$. By 1., $b = p_1 \cdots p_k \in H$, $c = p_{k+1} \cdots p_l \in H$ and clearly we have $a = bc$. Therefore $\beta$ is a transfer homomorphism, and thus Proposition 3.14 implies $\mathcal{L}(H) = \mathcal{L}(G_0)$.

3. Let $l \in \mathbb{N}_0$, $p_1, \ldots, p_l$ primes of $D$ and $u = p_1 \cdots p_l$ be an atom of $H$. Since $\beta$ is a transfer homomorphism, $\beta(u) = [p_1] \cdots [p_l] \in \mathcal{A}(G_0)$, and hence $D(G_0) \geq |\beta(u)| = l$. Conversely, let $U = g_1 \cdots g_l \in \mathcal{A}(G_0)$ with $D(G_0) = |U| = l$. If $p_i \in G_0$ with $g_i = [p_i]$ for $i \in [1, l]$, then $u = p_1 \cdots p_l$ is an atom of $H$ which is a product of $l$ primes of $D$.

4. The proof is not difficult but requires concepts not introduced here (see [71, Theorem 3.1.40]).

The homomorphism $\beta : H \to B(G_0)$ is called the block homomorphism of $H$. It transports arithmetical problems in $H$ to zero-sum problems over $G$. In particular, if $a = p_1 \cdots p_l \in D$ is as above, then $a$ is an atom of $H$ if and only if $\beta(a)$ is a minimal zero-sum sequence.

The next result states that in a Krull monoid with finite class group all arithmetical invariants introduced so far are finite. The proof of finiteness is fairly simple. However, establishing the precise values of the invariants is a completely different task. It can be tackled with methods from additive group theory, and the remaining sections of this article will be devoted to that.

Theorem 3.17. Let $H$ be a Krull monoid with finite class group. Then $H$ is a locally tame FF-monoid with finite catenary degree $\pi(H)$, finite set of distances $\Delta(H)$, finite elasticity $\rho(H)$ and with $\rho_k(H) < \infty$ for all $k \in \mathbb{N}$.

Proof. We may suppose that $H$ is reduced. Let $D = \mathcal{F}(P)$ be a monoid of divisors of $H$, $G = D/H$ its class group and $G_0 \subset G$ the set of classes containing primes. We proceed in several steps.

$H$ is an FF-monoid. If $a \in H$, then there are primes $p_1, \ldots, p_l \in P$ such that $a = p_1 \cdots p_l$, and this is the only factorization of $a$ in $D$. Therefore every factorization $a = u_1 \cdots u_k$ of $a$ into atoms of $H$ corresponds uniquely to a partition

$$[1, l] = \bigcup_{\nu=1}^k I_\nu,$$

where $\sum_{j \in I_\nu} [p_j] = 0 \in G$ but $\sum_{j \in I_\nu} [p_j] \neq 0 \in G$.

for all nonempty proper subsets $I_\nu \subset I_\nu$ and all $\nu \in [1, k]$. Thus $a$ has only finitely many factorizations in $H$.

$H$ is locally tame. Let $u = p_1 \cdots p_l \in \mathcal{A}(H)$ with $l \in \mathbb{N}$ and $p_1, \ldots, p_l \in P$. We assert that

$$t(H, u) \leq 1 + \frac{\lceil D(G_0) - 1 \rceil}{2} \leq 1 + \frac{D(G_0)(D(G_0) - 1)}{2}.$$

The second inequality follows from Theorem 3.16.3 and provides a global bound for all local tame degrees $t(H, u)$ with $u \in \mathcal{A}(H)$. So we have to verify the first inequality. If $u$ is a prime in $H$, then $t(H, u) = 0$ by definition. Suppose that $u$ is not a prime in $H$, that is $u \notin P$. Then $D(G_0) \geq l \geq 2$. We recall two
notations. If \( c \in D = \mathcal{F}(P) \), then \( c = q_1 \cdots q_s \), where \( s \in \mathbb{N}_0 \) and \( q_1, \ldots, q_s \in P \), and \( |c|_D = s \). If \( w \in Z(H) = \mathcal{F}(\mathcal{A}(H)) \), then \( w = v_1 \cdots v_t \), where \( t \in \mathbb{N}_0 \) and \( v_1, \ldots, v_t \in \mathcal{A}(H) \), and \( |w| = t \).

Let \( a \in H \), with \( u \ | a \) and \( z = u_1 \cdots u_r \in Z(a) \), where \( r \in \mathbb{N} \) and \( u_1, \ldots, u_r \in \mathcal{A}(H) \). We must prove that there exists some \( z' \in Z(a) \cap uZ(H) \) such that

\[
d(z, z') \leq 1 + \frac{l(D(G_0) - 1)}{2}.
\]

After renumbering if necessary we may assume that there exists some \( k \in [1, r] \) such that \( k \leq l \), \( u \ | u_1 \cdots u_k \), but \( u \) does not divide any proper subproduct of \( u_1 \cdots u_k \) (in \( D \) and hence in \( H \)). Since \( u \not\in P \), it follows that \( u_1, \ldots, u_k \not\in P \), and thus \( u_1, \ldots, u_k \) is not divisible by any \( p \in P \cap H \). If \( u_1, \ldots, u_k = uc \), where \( c \in H \), and if \( w \in Z(c) \), then \( |c|_D \geq 2|w| \) and

\[
|w| \leq \frac{|c|_D}{2} = \frac{|u_1|_D + \cdots + |u_k|_D - |u|_D}{2} \leq \frac{kD(G_0) - l}{2} \leq \frac{l(D(G_0) - 1)}{2}.
\]

Now it follows that \( z' = uw_1u_2 \cdots u_r \in Z(a) \), and

\[
d(z, z') \leq \max(k, |w| + 1) \leq \max(l, |w| + 1) \leq 1 + \frac{l(D(G_0) - 1)}{2}.
\]

On the remaining invariants. By Theorem 3.16, we have \( \Delta(H) = \Delta(G_0) \), \( c(H) \leq \max \{c(G_0), 2\} \), \( \rho(H) = \rho(G_0) \) and \( \rho_k(H) = \rho_k(G_0) \) for all \( k \in \mathbb{N} \), and hence it suffices to consider \( B(G_0) \). Clearly, we have \( \Delta(G_0) \subset \Delta(G) \), \( c(G_0) \leq c(G) \), \( \rho(G_0) \leq \rho(G) \) and \( \rho_k(G_0) \leq \rho_k(G) \) for all \( k \in \mathbb{N} \). For these latter invariants we shall derive explicit upper bounds and in some cases even precise values in Section 4.C.

### 3.D Main problems in factorization theory

1. Which noetherian domains satisfy the main finiteness properties of factorization theory: local tameness, finiteness of the catenary degree and the Structure Theorem for Sets of Lengths? (see Definition 5.8 and the subsequent results).

The goal is to derive explicit characterizations in terms of ring invariants. A prototype of such a result may be found in [96, Theorem 6.1]. It provides an explicit ring theoretical characterization of those finitely generated domains having finite elasticity.

2. If \( R \) is a ring of integers of an algebraic number field, then almost all elements of \( R \) have catenary degree at most 3 (see Corollary 5.13). Which other domains have such a property? Of course, "almost all" has to be interpreted in a suitable way: i.e., for orders in global fields in the sense of Dirichlet density and for \( \mathbb{Q} \)-algebras in the sense of Zariski density.

3. Let \( H \) be a Krull monoid with finite class group \( G \) such that every class contains a prime (the multiplicative monoid of non-zero elements of a ring of integers of an algebraic number field is such a Krull monoid).

Find the precise values of arithmetical invariants of \( H \) (such as \( c(H), \Delta(H) \) and \( \rho_k(H) \) for \( k \in \mathbb{N} \)) in terms of the group invariants of \( G \) (see [71, Chapter 6], and note that by the simple Theorem 3.17 all the invariants are finite). Results of this type are substantial for making progress on the Characterization Problem described in 5.C.

Let \( R \) be a noetherian domain. If \( R \) is integrally closed, then its multiplicative monoid \( R^* \) is a Krull monoid. Suppose that \( R \) is not integrally closed. If the integral closure \( \overline{R} \) is a finitely generated \( R \)-module and some further natural finiteness conditions hold, then the arithmetic of \( R \) is studied via \( \mathbb{C} \)-monoids and weakly \( \mathbb{C} \)-monoids. These monoids play a similar role as the monoid of zero-sum sequences does for Krull monoids (see [71, Theorems 2.11.9 and 3.3.4] and [73]).
However, in the present article we restrict to Krull monoids and focus on Problem 3, with respect to the invariants $\Delta(H)$, $c(H)$ and $\rho_k(H)$ for all $k \in \mathbb{N}$.

4. The Davenport constant and first precise arithmetical results

In this section we study the Davenport constant, a classical combinatorial invariant which has been investigated since the 1960s (see [115], [105], [31], [108] and [103]). From the very beginning the investigation of this invariant was related also to arithmetical problems (it is reported in [108] that in 1966 it was investigated since the 1960s (see [115], [105], [31], [108] and [103]). From the very beginning the investigation of this invariant was related also to arithmetical problems (it is reported in [108] that in 1966 it was investigated since the 1960s (see [115], [105], [31], [108] and [103]).

We shall determine the precise value of the Davenport constant among others for $p$-groups and for groups of rank at most two (see Theorems 4.10 and 6.13 and Corollary 6.16). For general finite abelian groups the precise value is still unknown. After that we put the Davenport constant in connection to the arithmetical invariants introduced in Section 3.

4.A The Davenport constant

We set $G^* = G \setminus \{0\}$. Let $G_0 \subseteq G$ be a subset and

$$S = \prod_{g \in G_0} g^{\nu_g(S)} = g_1 \cdots g_t \in \mathcal{F}(G_0)$$

a sequence over $G_0$. We call $\nu_g(S)$ the multiplicity of $g$ in $S$, and we say that $S$ contains $g$ if $\nu_g(S) > 0$. $S$ is called squarefree (in $\mathcal{F}(G)$) if $\nu_g(S) \leq 1$ for all $g \in G$. A sequence $S_1$ is called a subsequence of $S$ if $S_1 \mid S$ in $\mathcal{F}(G)$ (equivalently, $\nu_g(S_1) \leq \nu_g(S)$ for all $g \in G$), and it is called a proper subsequence of $S$ if it is a subsequence with $1 \neq S_1 \neq S$. We call

$$|S| = t = \sum_{g \in G_0} \nu_g(S) \in \mathbb{N}_0$$

the length of $S$,

$$h(S) = \max \{\nu_g(S) \mid g \in G\} \in [0, |S|]$$

the maximum of the multiplicities of $S$,

$$\text{supp}(S) = \{g \in G \mid \nu_g(S) > 0\} \subseteq G$$

the support of $S$.

$$\Sigma_k(S) = \left\{\sum_{i \in I} g_i \mid I \subseteq [1, t] \text{ with } |I| = k \right\}$$

the set of $k$-term subsums of $S$, for all $k \in \mathbb{N}$,

$$\Sigma_{\leq k}(S) = \bigcup_{j \in [1, k]} \Sigma_j(S), \quad \Sigma_{\geq k}(S) = \bigcup_{j \geq k} \Sigma_j(S),$$

and

$$\Sigma(S) = \Sigma_{\geq 1}(S)$$

the set of (all) subsums of $S$.

We set $-S = (-g_1) \cdots (-g_t)$, and for every $g \in G$ we set $g + S = (g + g_1) \cdots (g + g_t)$.

A sequence $S$ is called zero-sum free if $0 \notin \Sigma(S)$, and we denote by $A^*(G_0)$ the set of all zero-sum free sequences. Since every zero-sum free sequence $S$ is a subsequence of

$$\prod_{g \in G_0} g^{\nu_g(S) - 1},$$

$A^*(G_0)$ is finite. For convenience we introduce the following technical variant of the Davenport constant $D(G_0)$ (introduced in Definition 3.15), and in Lemma 4.2.3 we give a straightforward characterization.
Definition 4.1. Let \( G_0 \subset G \) be a nonempty subset. Then
\[
d(G_0) = \max \{ |S| \mid S \in \mathcal{F}(G_0) \text{ is zero-sum free} \} \in \mathbb{N}_0
\]
is called the \textit{little Davenport constant} of \( G_0 \).

Obviously, the map \( \psi: A^*(G_0) \rightarrow A^*(G) \), defined by \( S \mapsto (-\sigma(S))S \), is well-defined, and \( D(G_0) \leq 1 + d(G_0) \). If \( G_0 = G \), then \( \psi \) is surjective and \( D(G) = 1 + d(G) \). The following two lemmas gather some elementary properties of the Davenport constant.

Lemma 4.2. 

1. If \( S \in A^*(G) \) has length \( |S| = d(G) \), then \( \Sigma(S) = G^* \) and \( G = \langle \text{supp}(S) \rangle \).
2. \( d(G) = \max \{|S| \mid S \in \mathcal{F}(G), \Sigma(S) = G^* \} \).
3. \( D(G) \) is the smallest integer \( l \in \mathbb{N} \) such that every sequence \( S \in \mathcal{F}(G) \) of length \( |S| \geq l \) has a nontrivial zero-sum subsequence (that is, \( S \notin A^*(G) \)).
4. If \( S \in A^*(G) \), then \( |S| \leq |\Sigma(S)| \leq |G| - 1 \). In particular, \( d(G) \leq |G| - 1 \) and \( D(G) \leq |G| \).

Proof. 1. Let \( S \in A^*(G) \) with \( |S| = d(G) \), and assume that there is some \( h \in G^* \setminus \Sigma(S) \). Then \( T = (-h)S \in A^*(G) \) and \( |T| = 1 + |S| \), which contradicts the maximal choice of \( S \). Clearly, \( \Sigma(S) = G^* \) implies \( G = \langle \text{supp}(S) \rangle \).
2. If \( S \in \mathcal{F}(G) \) and \( \Sigma(S) = G^* \), then \( S \in A^*(G) \), and thus \( |S| \leq d(G) \). Conversely, if \( S \in A^*(G) \) and \( |S| = d(G) \), then \( \Sigma(S) = G^* \) by 1.
3. By definition we have \( d(G) = \max \{|S| \mid S \in A^*(G) \} \). Hence \( D(G) = d(G) + 1 \) is the smallest integer \( l \in \mathbb{N} \) such that every sequence \( S \in \mathcal{F}(G) \) with \( |S| \geq l \) does not lie in \( A^*(G) \).
4. If \( S = g_1 \ldots g \in A^*(G) \), then \( C = \{g_1 + \ldots + g_k \mid k \in [1, l] \} \subseteq \Sigma(S) \subseteq G^* \), and therefore \( |S| = |C| \leq |\Sigma(S)| \leq |G| - 1 \). Hence \( d(G) \leq |G| - 1 \), and thus \( D(G) \leq |G| \). \( \square \)

Let \( r \in \mathbb{N} \). An \( r \)-tuple \( (e_1, \ldots, e_r) \) of elements of \( G^* \) (resp. the elements \( e_1, \ldots, e_r \)) is said to be \textit{independent} if for every \( (m_i)_{i \in [1, r]} \in \mathbb{Z}^r \)
\[
\sum_{i=1}^r m_i e_i = 0 \quad \text{implies that} \quad m_1 e_1 = \ldots = m_r e_r = 0
\]
(equivalently, \( (e_1, \ldots, e_r) = (e_1) \oplus \ldots \oplus (e_r) \)). Moreover, \( (e_1, \ldots, e_r) \) is called a \textit{basis} of \( G \) if \( (e_1, \ldots, e_r) \) is independent and \( \{e_1, \ldots, e_r\} \) generates \( G \).

Suppose that \( |G| > 1 \). Then by the Structure Theorem of Finite Abelian Groups, we have
\[
G \cong C_{n_1} \oplus \ldots \oplus C_{n_r}
\]
where \( 1 < n_1 | \ldots | n_r, r = r(G) \) is the \textit{rank} of \( G \) and \( n_r = \exp(G) = \text{lcm}\{\text{ord}(g) \mid g \in G \} \) is the \textit{exponent} of \( G \). We define
\[
d^*(G) = \sum_{i=1}^r (n_i - 1),
\]
and we set \( d^*(\{0\}) = 0 \). \( G \) is called an \textit{(elementary) \( p \)-group} if \( \exp(G) \) is a power of \( p \) (resp. \( \exp(G) \mid p \)).

Lemma 4.3. \( \exp(G) = n \geq 2 \).

1. If \( e_1, \ldots, e_r \in G \) are independent elements, then
\[
S = \prod_{i=1}^r e_i^{\text{ord}(e_i) - 1} \in A^*(G).
\]
2. There exists a sequence \( S \in A^*(G) \) such that \( |S| = d^*(G) \). In particular, \( d^*(G) \leq d(G) \).
Proof. 1. If \( 1 \neq T \) is a a subsequence of \( S \), then \( T = e_1^{k_1} \cdots e_r^{k_r} \) where \( k_i \in [0, \text{ord}(e_i) - 1] \) for all \( i \in [1, r] \) and \( k_i > 0 \) for at least one \( i \in [1, r] \). Hence \( \sigma(T) = k_1 e_1 + \cdots + k_r e_r \neq 0 \), and thus \( S \) is zero-sum free.

2. If \( G \cong C_{n_1} \oplus \cdots \oplus C_{n_r} \), where \( 1 < n_1 | \cdots | n_r \), and \( \{ e_1, \ldots, e_r \} \) is a basis of \( G \) such that \( \text{ord}(e_i) = n_i \) for all \( i \in [1, r] \), then \( S = e_1^{n_1-1} \cdots e_r^{n_r-1} \in \mathcal{A}(G) \) by 1., and hence \( d^*(G) = |S| \leq d(G) \). \( \square \)

Corollary 4.4.

1. Let \( G \) be cyclic of order \( n \geq 2 \). A sequence \( S \in \mathcal{F}(G) \) is zero-sum free of length \( |S| = d(G) \) if and only if \( S = g^{ord(g)} \) for some \( g \in G \) with \( \text{ord}(g) = n \). In particular, \( d(G) = d^*(G) = n - 1 \) and \( D(G) = n \).

2. Let \( G \) be an elementary 2-group. A sequence \( S \in \mathcal{F}(G) \) is zero-sum free if and only if \( S \) is squarefree and \( \text{supp}(S) \) is an independent set. In particular, \( d(G) = d^*(G) = r(G) \).

Proof. 1. By Lemmas 4.2 and 4.3, we have \( n - 1 = d^*(G) \leq d(G) \leq |G| - 1 = n - 1 \) and thus \( d(G) = n - 1 \) and \( D(G) = n \). Obviously, if \( g \in G \) with \( \text{ord}(g) = n \), then \( S = g^{ord(g)} \in \mathcal{A}^*(G) \). Conversely, assume to the contrary that \( S = g_1 \cdots g_{n-1} \in \mathcal{A}^*(G) \) and \( g_1 \neq g_2 \). If \( \Sigma = \{g_1 + \cdots + g_k \mid k \in [1, n-1]\} \), then \( |\Sigma| = n - 1 \) and \( g_2 \notin \Sigma \), a contradiction.

2. If \( S \) is squarefree and \( \text{supp}(S) \) is independent, then \( S \) is zero-sum free by Lemma 4.3.1. Conversely, if \( S \in \mathcal{A}^*(G) \), then \( m(S) < \text{ord}(g) \) for all \( g \in \text{supp}(S) \). Hence \( S \) is squarefree, and \( 0 \notin \Sigma(S) \) implies that \( \text{supp}(S) \) is independent.

Thus we get \( d(G) = r(G) \), and by the very definitions, it follows that \( d^*(G) = r(G) \). \( \square \)

There is a weighted version of the Davenport constant, called the cross number, which plays a crucial role in factorization theory (in particular, in the investigations of half-factorial and minimal non-half-factorial subsets, see [71, Chapter 5], [110, 111] and [76, 77] for recent progress).

4.B Group algebras

Group algebras \( R[G] \) - over suitable commutative rings \( R \) - have turned out to be powerful tools for a growing variety of questions from combinatorics and number theory. We discuss the classical application of group algebras to the investigation of zero-sum free sequences over \( p \)-groups, which is due to P. van Emde Boas, D. Kruyswijk and J.E. Olson. Theorem 4.10 provides the classical result that for a \( p \)-group \( G \) we have \( d(G) = d^*(G) \).

Let \( R \) be a commutative ring (throughout, we assume that \( R \) has a unit element \( 1 \neq 0 \)). The group algebra \( R[G] \) of \( G \) over \( R \) is a free \( R \)-module with basis \( \{X^g \mid g \in G\} \), where multiplication is defined by

\[
\left( \sum_{g \in G} a_g X^g \right) \left( \sum_{g \in G} b_g X^g \right) = \sum_{g \in G} \left( \sum_{h \in G} a_h b_{g-h} \right) X^g.
\]

In particular, \( X^g X^h = X^{g+h} \) for all \( g, h \in G \). Thus we can think of this as a generalization of a polynomial ring, where the exponents come from the group \( G \) rather than from \( \mathbb{N}_0 \). Moreover, we view \( R \) as a subset of \( R[G] \) by means of \( a = a X^0 \) for all \( a \in R \). The augmentation map

\[
\varepsilon : R[G] \to R, \quad \text{defined by} \quad \varepsilon \left( \sum_{g \in G} a_g X^g \right) = \sum_{g \in G} a_g
\]

is an epimorphism of \( R \)-algebras, and its kernel \( \text{Ker}(\varepsilon) = I_G \) is called the augmentation ideal.

Definition 4.5. For a commutative ring \( R \), let \( d(G, R) \) denote the largest integer \( l \in \mathbb{N} \) having the following property:

There is some sequence \( S = g_1 \cdots g_l \) of length \( l \) over \( G \) such that

\[
(a_1 - X^{g_1}) \cdots (a_l - X^{g_l}) \neq 0 \in R[G] \quad \text{for all} \quad a_1, \ldots, a_l \in R^*.
\]
Lemma 4.6. Let $R$ be an integral domain, $S = g_1 \cdots g_r \in \mathcal{F}(G)$ a zero-sum free sequence and $a_1, \ldots, a_l \in R^\ast$. If
\[
f = \prod_{i=1}^l (a_i - X^{\beta_i}) = \sum_{g \in G} c_g X^g \in R[G] \quad \text{with} \quad c_g \in R \quad \text{for all} \quad g \in G,
\]
then $c_0 \neq 0$, and hence $f \neq 0$. In particular, we have $d(G) \leq d(G, R)$.

Proof. Since $R$ is an integral domain and $0 \notin \Sigma(S)$, it follows that $c_0 = a_1 \cdots a_l \neq 0$. \hfill \Box

Definition 4.7. Let $S = g_1 \cdots g_r \in \mathcal{F}(G)$ be a sequence of length $|S| = l \in \mathbb{N}_0$ and let $g \in G$.

1. For every $k \in \mathbb{N}_0$ let
\[
N^k_g(S) = \left\{ I \subset [1, l] \mid \sum_{i \in I} g_i = g \quad \text{and} \quad |I| = k \right\}
\]
denote the number of subsequences $T$ of $S$ having sum $\sigma(T) = g$ and length $|T| = k$ (counted with the multiplicity of their appearance in $S$).

2. We define $N_g(S) = \sum_{k \geq 0} N^k_g(S), \quad N^+_g(S) = \sum_{k \geq 0} N^{2k}_g(S) \quad \text{and} \quad N^-_g(S) = \sum_{k \geq 0} N^{2k+1}_g(S)$. Thus $N_g(S)$ denotes the number of subsequences $T$ of $S$ having sum $\sigma(T) = g$. $N^+_g(S)$ denotes the number of all such subsequences of even length, and $N^-_g(S)$ denotes the number of all such subsequences of odd length (each counted with the multiplicity of its appearance in $S$).

Lemma 4.8. Let $p$ be a prime and $G$ a $p$-group. Then the following identities hold in $F_p[G]$.

1. If $g \in G$ and $\text{ord}(g) = m \geq 2$, then
\[
(1 - X^g)^m = 0 \in F_p[G], \quad (1 - X^g)^{m-1} = \sum_{j=0}^{m-1} X^{gj} \in F_p[G]
\]
and
\[
(1 - X^g)^{m-2} = \sum_{j=0}^{m-1} (j + 1)X^{gj} \in F_p[G].
\]

2. Let $(e_1, \ldots, e_r)$ be a basis of $G$ and $\text{ord}(e_i) = n_i \geq 2$ for all $i \in [1, r]$. Then
\[
\prod_{i=1}^r (1 - X^{e_i})^{m-1} = \sum_{g \in G} X^g \in F_p[G],
\]
and if $m \in \mathbb{N}$ and $g_1, \ldots, g_m \in G$, then
\[
\prod_{u=1}^m (1 - X^{g_u}) = \sum_{j=1}^r c_j \prod_{i=1}^r (1 - X^{e_i})^{l_{j,i}} \in F_p[G],
\]
where $t \in \mathbb{N}_0$, $c_j \in F_p$, $l_{j,1}, \ldots, l_{j,r} \in \mathbb{N}_0$ and $l_{j,1} + \ldots + l_{j,r} \geq m$ for all $j \in [1, t]$.

Proof. 1. Since $m$ is a power of $p$, we obtain $(1 - X^g)^m = 1 - X^{mg} = 0 \in F_p[G]$. For $k \in \{1, 2\}$, we have
\[
(1 - X^g)^{m-k} = \sum_{j=0}^{m-k} \binom{m-k}{j} (-1)^j X^{gj}. \]
We assert that, for every $j \in [0, m - 1]$, 
\[
\binom{m-1}{j} (-1)^j \equiv 1 \mod p \quad \text{and} \quad \binom{m-2}{j} (-1)^j \equiv (j + 1) \mod p.
\]

Indeed, in the polynomial ring $F_p[T]$ we have
\[
\sum_{j=0}^{m-1} \binom{m-1}{j} (-1)^j T^j = (1 - T)^{m-1} = \frac{(1 - T)^m}{1 - T} = \frac{1 - T^m}{1 - T} = \sum_{j=0}^{m-1} T^j,
\]
whence the first assertion follows. Since
\[
\binom{m-2}{j} = \binom{m-1}{j} \cdot \frac{m-j-1}{m-1} \equiv (j+1) \binom{m-1}{j} \mod p,
\]
the second assertion follows.

2. Every $g \in G$ has a unique representation of the form $g = v_1 e_1 + \ldots + v_r e_r$, where $v_i \in [0, n_i - 1]$ for all $i \in [1, r]$. Therefore 1. implies that
\[
\prod_{i=1}^{r} (1 - X^{e_i})^{n_i-1} = \prod_{i=1}^{r} \sum_{n=0}^{n_i-1} X^n e_i = \sum_{g \in G} X^g.
\]

For the proof of the second identity we define, for every $l = (l_1, \ldots, l_r) \in N_0^r$,
\[
g_l = \prod_{i=1}^{r} (1 - X^{e_i})^{l_i}.
\]

The augmentation ideal $I_G$ is generated by $\{g_l \mid 0 \neq l \in N_0^r\}$. For $\mu \in [1, m]$ we have $1 - X^{g_\mu} \in I_G$ and therefore
\[
1 - X^{g_\mu} = \sum_{0 \neq l \in N_0^r} c_{\mu, l} g_l
\]
with coefficients $c_{\mu, l} \in F_p$. Hence
\[
\prod_{\mu=1}^{m} (1 - X^{g_\mu}) = \sum_{0 \neq l_1, \ldots, l_m \in N_0^r} c_{l_1, \ldots, l_m, g_1, \ldots, g_m},
\]
and $|l_1 + \ldots + l_m| \geq m$ for all $l_1, \ldots, l_m \in N_0^r \setminus \{0\}$. \qed

Lemma 4.9. Let $p$ be a prime, $G$ a $p$-group, $S = g_1 \cdot \ldots \cdot g_l \in \mathcal{F}(G)$, and 
\[
f = \prod_{i=1}^{l} (1 - X^{g_i}) = \sum_{g \in G} c_g(S) X^g \in F_p[G] .
\]

1. For every $g \in G$, we have $c_g(S) = N^+_g(S) - N^-_g(S) + p\mathbb{Z} \in F_p$. In particular, if $c_0(S) = 0$, then $0 \in \Sigma(S)$, and if $g \in G^{\ast}$ and $c_g(S) \neq 0$, then $g \in \Sigma(S)$.

2. For $i \in [1, l]$, let $g_i = p^{m_i} g_i'$ with $g_i' \in G$ and $m_i \in \mathbb{N}_0$, and define 
\[
m = \sum_{i=1}^{l} p^{m_i}.
\]

If $m > d^*(G)$, then $c_g(S) = 0$ for all $g \in G$, $0 \in \Sigma(S)$, and in particular $N^+_g(S) \equiv N^-_g(S) \mod p$ for all $g \in G$. 

Proof. 1. For \( g \in G \), we set

\[
\Omega_g = \{ f \subset [1, t] \mid \sum_{i \in f} g_i = g \}.
\]

Then \( \emptyset \in \Omega_0 \) and

\[
c_g(S) = \sum_{J \in \Omega_g} (-1)^{|J|} + p\mathbb{Z} = N^+_g(S) - N^-_g(S) + p\mathbb{Z} \in \mathbb{F}_p.
\]

Hence \( c_0(S) = 0 \) implies \( 0 \in \Sigma(S) \), and if \( g \in G^* \) is such that \( c_g(S) \neq 0 \), then \( g \in \Sigma(S) \).

2. We shall repeatedly make use of Lemma 4.8. Let \((e_1, \ldots, e_r)\) be a basis of \( G \), \( \text{ord}(e_i) = n_i \) for all \( i \in \{1, \ldots, r\} \), and \( 1 < n_1 | \ldots | n_r \). Then

\[
d^*(G) = (n_1 - 1) + \ldots + (n_r - 1).
\]

For \( i \in \{1, \ldots, r\} \) we have \((1 - X^{e_i})^m = 1 - X^{m e_i} = 1 - X^{g_i} \), and therefore

\[
f = \prod_{i=1}^t (1 - X^{e_i})^m = \prod_{j=1}^t \prod_{i=1}^{l_j} (1 - X^{e_i})^{l_{j,i}}
\]

for some \( t \in \mathbb{N}_0 \), \( c_1, \ldots, c_r \in \mathbb{F}_p \), \( l_{j,i} \in \mathbb{N}_0 \) and \( l_{j,1} + \ldots + l_{j,r} \geq m \) for all \( j \in \{1, \ldots, t\} \). If \( j \in \{1, \ldots, t\} \) and \( l_{j,i} \geq n_i \) for some \( i \in \{1, \ldots, r\} \), then

\[
\prod_{i=1}^{l_{j,i}} (1 - X^{e_i})^{l_{j,i}} = 0 \in \mathbb{F}_p[G].
\]

Hence we may assume that \( l_{j,i} < n_i \) for all \( i \in \{1, \ldots, r\} \) and \( j \in \{1, \ldots, t\} \), and then either \( t = 0 \) or \( m \leq l_{j,1} + \ldots + l_{j,r} \leq d^*(G) \) for all \( j \in \{1, \ldots, t\} \).

If \( m > d^*(G) \), then \( t = 0 \), hence \( f = 0 \), and thus \( c_g(S) = 0 \) for all \( g \in G \). The remaining assertions follow by 1. \( \square \)

Theorem 4.10. If \( G \) is a \( p \)-group, then \( d^*(G) = d(G) = d(G, F_p) \).

Proof. Suppose that \( G \) is a \( p \)-group. Lemmas 4.3.2 and 4.6 imply that \( d^*(G) \leq d(G) \leq d(G, F_p) \). If \( S = g_1 \cdot \ldots \cdot g_t \in \mathcal{F}(G) \) with \( |S| = t > d^*(G) \), then Lemma 4.9.2 (with \( m_1 = \ldots = m_t = 0 \)) implies that

\[
(1 - X^{g_1}) \cdot \ldots \cdot (1 - X^{g_t}) = 0,
\]

and thus \( d(G, F_p) \leq d^*(G) \). \( \square \)

An alternate proof of Theorem 4.10 was given by Zhi-Wei Sun who used covers of the integers (see [128, Corollary 2.1]). Here we briefly discuss some extensions of the classical approach via group algebras.

Let \( G' \) be a finite abelian group. Then, by G. Higman's Theorem, \( \mathbb{Z}[G] \cong \mathbb{Z}[G'] \) implies that \( G \cong G' \) (see [106, Corollary 3.3.6 and Theorem 9.1.4]). Therefore any combinatorial problem in \( G \) can, at least in principle, be tackled via the group algebra \( \mathbb{Z}[G] \). Indeed, working over \( \mathbb{Z}[G] \) allows to refine the congruences involving \( N^+_g(S) \) and \( N^-_g(S) \), as obtained in Lemma 4.9.2 (see [52]).

Let \( \exp(G) = n \) and let \( K \) be a splitting field of \( G \) (that is \( \{ \zeta \in K \mid \zeta^n = 1 \} = n \) ). Following the ideas of P. van Emde Boas and using character theory, one obtains that

\[
d(G, K) \leq (n - 1) + n \log \frac{|G|}{n}
\]

(see [71, Theorem 5.5.5]). In particular, for cyclic group this implies that \( d(G) = d(G, K) = n - 1 \). W. Gao conjectures that for every \( G \) there is a splitting field \( F \) such that \( d(G) = d(G, F) \), and in [59] W. Gao and Y. Li showed that, for every splitting field \( K \) of \( G = C_2 \circ C_{2n} \) we have \( d(C_2 \circ C_{2n}, K) = d(C_2 \circ C_{2n}, K) \) (see also [55]).

4.4 Arithmetical invariants again
Theorem 4.11. Let $H$ be a Krull monoid with class group $G$ such that every class contains a prime and suppose that $|G| > 1$. Let $k \in \mathbb{N}$.

1. If $A = 0^m B \in G_1(G)$, with $m \in \mathbb{N}_0$ and $B \in G_1(G^*)$, then
   \[ 2 \max L(A) - m \leq |A| \leq D(G) \min L(A) - m(D(G) - 1) \quad \text{and} \quad \rho(A) \leq \frac{D(G)}{2}. \]

2. We have $k \leq \rho_k(H) \leq k \frac{D(G)}{2}$ and $\rho(H)^{-1} k \leq \lambda_k(H) \leq k$.

3. $\rho_k(H) = kD(G)$ and $\rho(H) = \frac{D(G)}{2}$.

4. If $j, l \in \mathbb{N}_0$ such that $lD(G) + j \geq 1$, then
   \[ 2l + \frac{2j}{D(G)} \leq \lambda_{lD(G)+j}(G) \leq 2l + j. \]

In particular, $\lambda_{lD(G)}(G) = 2l$ for every $l \in \mathbb{N}$.

Proof. By Theorem 3.16 it suffices to consider the block monoid $G_1(G)$.

1. Let $A = 0^m U_1 \cdot \ldots \cdot U_l$ where $l, m \in \mathbb{N}_0$ and $U_1, \ldots, U_l \in G_1(G^*)$. Then $2 \leq |U_\nu| \leq D(G)$ for all $\nu \in \{1, l\}$ and hence
   \[ m + 2l \leq |A| \leq m + lD(G). \]
Choosing $l = \max L(B)$ and $l = \max L(B)$ we obtain the first inequalities, and then we get
   \[ \rho(A) = \frac{\max L(A)}{\min L(A)} = \frac{m + \max L(B)}{m + \min L(B)} \leq \frac{\max L(B)}{\min L(B)} \leq \frac{D(G)}{2}. \]

2. By definition, we have $k \leq \rho_k(G)$.

3. By 1. and 2. it follows that $\rho_{lD(G)}(G) \leq kD(G)$ and $\rho(G) \leq \frac{D(G)}{2}$. If $U = g_1 \cdot \ldots \cdot g_l \in G_1(G)$ with $|U| = l = D(G)$, then
   \[ (-U)^k U^k = \prod_{\nu=1}^{l} (-g_\nu)^k, \]
shows that in both inequalities we actually have equality.

4. Let $j, l \in \mathbb{N}_0$ such that $lD(G) + j \geq 1$. Then 2. and 3. imply that
   \[ 2l + \frac{2j}{D(G)} = \rho(G)^{-1} (lD(G) + j) \leq \lambda_{lD(G)+j}(G) \leq lD(G) + j. \]
If $j = 0$, it follows that $\lambda_{lD(G)}(G) = 2l$. \hfill $\square$

Lemma 4.12.

1. For $j \in \mathbb{N}_{\geq 2}$, the following statements are equivalent:
   \begin{itemize}
   \item[(a)] There exists some $L \in \mathcal{L}(G)$ with $\{2, j\} \subseteq L$.
   \item[(b)] $j \leq D(G)$.
   \end{itemize}

2. Let $|G| \geq 3$ and $A \in G_1(G)$. Then $\{2, D(G)\} \subseteq \mathcal{L}(A)$ if and only if $A = U(-U)$ for some $U \in G_1(G)$ with $|U| = D(G)$.
Proof. 1. (a) \(\Rightarrow\) (b) If \(L \in \mathcal{L}(G) \) and \(\{2, j\} \subset L\), then Theorem 4.13 implies that \(j \leq \sup L \leq \rho_2(G) = D(G)\).

(b) \(\Rightarrow\) (a) If \(j \leq D(G)\), then there exists some \(U \in \mathcal{A}(G)\) with \(|U| = l \geq j\), say \(U = g_1 \cdot \ldots \cdot g_l\). Then \(V = g_1 \cdot \ldots \cdot g_{j-1}(g_j + \ldots + g_l) \in \mathcal{A}(G)\), and \(\{2, j\} \subset L(V(-V))\).

2. If \(\{2, D(G)\} \subset L(A)\), then there exist \(U_1, U_2, V_1, \ldots, V_{D(G)} \in A(G)\) such that \(A = U_1 U_2 = V_1 \cdot \ldots \cdot V_{D(G)}\), and clearly \(0 \notin A\), since otherwise \(U_1 = 0\) or \(U_2 = 0\) and \(D(G) = 2\). Theorem 4.11 implies that \(\max L(A) = D(G)\) and \(|A| = 2D(G)\). Hence \(|V_i| = 2\) for all \(i \in [1, D(G)]\), and \(|U_1| = |U_2| = D(G)\), which implies \(U_2 = -U_1\). The converse is obvious. \(\Box\)

Lemma 4.13. Suppose that \(d \in \mathbb{N}\) has the following property:

For all \(U, V \in A(G)\) with \(\min \{|U|, |V|\} > d\), there exists a factorization \(UV = W_1 \cdot \ldots \cdot W_k\), with \(k \in [2, d]\), and \(|W_1| \leq d\).

Then \(c(G) \leq d\).

Proof. We must prove that \(c(A) \leq d\) for all \(A \in \mathcal{B}(G)\). We proceed by induction on \(|A|\), and we must prove that any two factorizations of \(A\) can be concatenated by a \(d\)-chain. Let \(z, z'\) be two factorizations of \(A\), say

\[z = U_1 \cdot \ldots \cdot U_r \quad \text{and} \quad z' = V_1 \cdot \ldots \cdot V_s,\]

where \(U_1, \ldots, U_r, V_1, \ldots, V_s \in \mathcal{A}(G)\).

If \(\max \{r, s\} \leq d\), then \(d(z, z') \leq d\) and we are done. Assume that \(r > d\).

CASE 1: \(|V_1| \leq d\) for some \(i \in [1, s]\), say \(|V_1| \leq d\).

We may assume that \(V_1 | U_1 \cdot \ldots \cdot U_{r-1}\), say \(U_1 \cdot \ldots \cdot U_{r-1} = V_1 W_1 \cdot \ldots \cdot W_l\), with \(l \in \mathbb{N}\) and \(W_1, \ldots, W_l \in A(G)\). By the induction hypothesis there is a \(d\)-chain of factorizations \(y_0, \ldots, y_k\) concatenating \(U_1 \cdot \ldots \cdot U_{r-1}\) and \(V_1 W_1 \cdot \ldots \cdot W_l\), and there is a \(d\)-chain of factorizations \(z_0, \ldots, z_l\) concatenating \(W_1 \cdot \ldots \cdot W_l U_r\) and \(V_2 \cdot \ldots \cdot V_s\). Then \(z = y_0 U_r, \ldots, y_k U_r = z_0 V_1, \ldots, z_l V_1 = z'\) is a \(d\)-chain concatenating \(z\) and \(z'\).

CASE 2: \(|V_1| > d\) for all \(i \in [1, s]\).

By assumption there is a factorization \(V_1 V_2 = W_1 \cdot \ldots \cdot W_k\), with \(k \in [2, d]\) and \(|W_1| \leq d\). Then the factorization \(z'' = W_1 \cdot \ldots \cdot W_k V_3 \cdot \ldots \cdot V_s\) of \(A\) satisfies \(d(z', z'') = \max \{2, k\} \leq d\), and by CASE 1 there is a \(d\)-chain of factorizations concatenating \(z\) and \(z''\). \(\Box\)

Theorem 4.14. Let \(H\) be a Krull monoid with class group \(G\).

1. \(c(H) \leq D(G)\).

2. Suppose that \(|G| \geq 3\). Then \(c(G) = D(G)\) if and only if \(G\) is either cyclic or an elementary 2-group.

Proof. 1. By Theorem 3.16 it suffices to show that \(c(G) \leq D(G)\). This follows immediately from Lemma 4.13 with \(d = D(G)\).

2. If \(G\) is cyclic, \(g \in G\) with \(\text{ord}(g) = n = |G|\) and \(U = g^n\), then \(c((-U)|U|) = n\) and hence \(c(G) = D(G)\). If \(G\) is an elementary 2-group with basis \((e_1, \ldots, e_r)\), \(e_0 = e_1 + \ldots + e_r\) and \(U = e_0 \cdot \ldots \cdot e_r\), then \(c(U^2) = r + 1 = D(G)\) and hence \(c(G) = D(G)\).

Assume now that \(G\) is neither cyclic nor an elementary 2-group. We shall prove that for all \(U, V \in A(G)\) with \(|U| = |V| = D(G)\) there exists some factorization \(UV = W_1 \cdot \ldots \cdot W_k\) with \(k \in [2, d(G)]\) and \(|W_1| \leq d(G)\). Then \(c(G) \leq d(G)\) by Lemma 4.13.

Let \(U, V \in A(G)\) with \(|U| = |V| = D(G)\). Then \(\max L(UV) \leq D(G)\), and equality holds if and only if \(V = -U\) (cf. Lemma 4.12). Now we distinguish two cases.

CASE 1: \(V \neq -U\).

It is sufficient to prove that there exists some \(W \in A(G)\) such that \(W|UV\) and \(|W| < D(G)\). Assume the contrary. Let \(g \in \text{supp}(U)\) and \(V = h_1 \cdot \ldots \cdot h_l\) with \(l = D(G)\). For every \(i \in [1, l]\), we consider the
sequence $S_i = gh^{-1}V \in \mathcal{F}(G)$. Since $|S_i| = D(G)$, there exists some $\mathcal{F}(G)$ such that $S_i \in \mathcal{A}(G)$ such that $S_i | S_i | UV$. By assumption, this implies $|S_i| = D(G)$, hence $S_i = S_i$ and therefore $0 \sigma(S_i) = g - h_i$. Thus $V = g$, and Lemma 4.2.1 implies $G = \langle \supp(V) \rangle = \langle g \rangle$, a contradiction.

CASE 2: $V = -U$.

It is sufficient to prove that there exists some $W \in \mathcal{A}(G)$ such that $W \mid U(-U)$ and $2 < |W| < D(G)$. Then we consider any factorization $U(-U) = W_1 \cdots W_k$ with $W_1, \ldots, W_k \in \mathcal{A}(G)$, and obtain that $k < D(G)$.

By Lemma 4.2.1 we have $\langle \supp(U) \rangle = G$, and since $G$ is not an elementary 2-group, there exists some $g_0 \in \supp(U)$ with $\operatorname{ord}(g_0) > 2$. We set $U = g_0^{m_1} g_1 \cdots g_l$ with $g_0 \notin \{g_1, \ldots, g_l\}$. Since $G = \langle \supp(U) \rangle$ is not cyclic, it follows that $l \geq 2$. If $W' = (-g_0)^{m_1} g_1 \cdots g_l$, then $W' | U(-U)$ and $|W'| = D(G)$. Hence there exists some $W \in \mathcal{A}(G)$ with $W | W'$, and we shall prove that $2 < |W| < D(G)$. Since $U \in \mathcal{A}(G)$, we have $W \notdivides g_1 \cdots g_l$ and thus $-g_0 | W$. Since $g_0 \notin \{g_1, \ldots, g_l\}$ and $g_0 \neq -g_0$, it follows that $W \neq g_0(-g_0)$ and thus $|W| > 2$.

Assume to the contrary that $|W| = D(G)$. Then $W = W'$, and $\sigma(U) = \sigma(W) = 0$ implies $2m g_0 = 0$ and thus $m > 1$. We consider the sequence $S = g_0^{m_1} g_1 \cdots g_{l-1}$. Since $S \in \mathcal{A}(G)$ and $|S| = d(G)$, Lemma 4.2.1 implies $\Sigma(S) = G^*$ and thus $(m + 1)g_0 \in \Sigma(S)$, say

$$(m + 1)g_0 = s g_0 + \sum_{i \in I} g_i \quad \text{with} \quad s \in [0, m] \quad \text{and} \quad I \subseteq [1, l - 1].$$

If $s = 0$, then

$$0 = 2m g_0 = (m - 1)g_0 + \sum_{i \in I} g_i \in \Sigma(S),$$

a contradiction. If $s \geq 1$, then it follows that

$$T = (-g_0)^{m+1-s} \prod_{i \in I} g_i$$

is a proper zero-sum subsequence of $W$, a contradiction to $W \in \mathcal{A}(G)$. \qed

Corollary 4.15. Let $H$ be a Krull monoid with class group $G$ such that every class contains a prime. Suppose that $|G| \geq 3$ and that $\exp(G) = n \geq 2$. Then

$$[1, n - 2] \subseteq \Delta(H) \subseteq [1, c(G) - 2] \subseteq [1, D(G) - 2].$$

In particular, if $G$ is cyclic, then $\Delta(H) = [1, n - 2]$.

Proof. By Theorem 3.16, it suffices to consider the block monoid $B(G)$. Lemma 3.7.3 implies that $\Delta(G) \subseteq [1, c(G) - 2]$ and Theorem 4.14 that $c(G) \leq D(G)$.

Suppose that $n \geq 3$, pick $i \in [3, n]$ and $g \in G$ with $\operatorname{ord}(g) = n$. Then $T = g^n, U = (i - 1)g, V = (-g)g$ and $W = g^n (i - 1)g$ are minimal zero-sum sequences. Then

$$TU = V^{i-1}W$$

shows that $L(TU) = \{2, i\}$ whence $i - 2 \in \Delta(L(TU)) \subseteq \Delta(G)$.

If $G$ is cyclic, then Corollary 4.4 implies that $D(G) = n$ and thus $\Delta(G) = [1, n - 2]$. \qed

For all groups known so far it always holds $\Delta(G) = [1, c(G) - 2]$.

Corollary 4.16. The following statements are equivalent:

(a) Every $L \in \mathcal{L}(G)$ with $\{2, D(G)\} \subseteq L$ satisfies $L \subseteq \{2, D(G)\}$.

(b) $\{2, D(G)\} \in \mathcal{L}(G)$.

(c) $G$ is either cyclic or an elementary 2-group.
Proof. \( (a) \Rightarrow (b) \) By Lemma 4.1.1 there exists some \( L \in \mathcal{L}(G) \) with \( \{2, D(G)\} \subseteq L \).

\( (b) \Rightarrow (c) \) If \( L = \{2, D(G)\} \in \mathcal{L}(G) \), then, by Lemma 3.7.3 and Theorem 4.1.4, we have \( D(G) \leq 2 + \sup \Delta(G) \leq c(G) \leq D(G) \), hence \( c(G) = D(G) \), and the assertion follows by Theorem 4.1.2.

\( (c) \Rightarrow (a) \) Let \( L \in \mathcal{L}(G) \) with \( \{2, D(G)\} \subseteq L \). By Lemma 4.1.2, we have \( L = L(U(-U)) \) for some \( U \in \mathcal{A}(G) \) with \( |U| = D(G) \).

If \( G \) is cyclic of order \( n \geq 3 \), then Corollary 4.4 implies that \( U = g^n \) for some \( g \in G \) with \( \text{ord}(g) = n \). Since \( \mathcal{A}([-g, g]) = \{(-g)^n, g^n, g(-g)\} \), it follows that \( L(U(-U)) = \{2, D(G)\} \).

If \( G \) is an elementary 2-group of rank \( r \geq 2 \) and \( (e_1, \ldots, e_r) \) is a basis of \( G \), then \( U = e_1 + \cdots + e_r \) by Corollary 4.4 and \( L(U(-U)) = \{2, r + 1\} = \{2, D(G)\} \).

\[ \square \]

5. The structure of sets of lengths

Sets of lengths in Krull monoids and in noetherian domains are finite and nonempty. Furthermore, either all sets of lengths are singletons or sets of lengths may become arbitrarily large (see Lemma 3.1).

5.1. Unions of sets of lengths

Definition 5.1. Let \( H \) be a BF-monoid and \( k \in \mathbb{N} \). Let \( \mathcal{V}_k(H) \) denote the set of all \( m \in \mathbb{N} \) for which there exist \( u_1, \ldots, u_k, v_1, \ldots, v_m \in \mathcal{A}(H) \) with \( u_1 \cdots u_k = v_1 \cdots v_m \).

Lemma 5.2. Let \( H \) be a BF-monoid with \( H \neq H^* \) and \( k, l \in \mathbb{N} \).

1. \( \mathcal{V}_1(H) = \{1\} \), \( k \in \mathcal{V}_k(H) \) and

\[ \mathcal{V}_k(H) = \bigcup_{k \in L, L \in \mathcal{L}(H)} L. \]

In particular, \( \rho_k(H) = \sup \mathcal{V}_k(H) \) and \( \lambda_k(H) = \min \mathcal{V}_k(H) \).

2. \( \mathcal{V}_k(H) + \mathcal{V}_l(H) \subseteq \mathcal{V}_{k+l}(H) \) and

\[ \lambda_{k+l}(H) \leq \lambda_k(H) + \lambda_l(H) \leq k + l \leq \rho_k(H) + \rho_l(H) \leq \rho_{k+l}(H). \]

3. We have \( l \in \mathcal{V}_k(H) \) if and only if \( k \in \mathcal{V}_l(H) \).

Proof. This follows immediately from the definitions. \[ \square \]

Thus the sets \( \mathcal{V}_k(H) \) are unions of sets of lengths. They were introduced by S.T. Chapman and W.W. Smith in 1990 (see [17]). The following result reveals that, in Krull monoids where every class contains a prime, the \( \mathcal{V}_k(H) \) sets are intervals. This was first shown in [35]. The following simple proof is due to F. Halter-Koch.

Theorem 5.3. Let \( H \) be a Krull monoid with finite class group \( G \) such that every class contains a prime. Then for every \( k \in \mathbb{N} \) the set \( \mathcal{V}_k(H) \) is an arithmetical progression with difference 1, and hence \( \mathcal{V}_k(H) = [\lambda_k(H), \rho_k(H)] \).

Proof. By Theorem 3.16, it suffices to consider the block monoid \( \mathcal{B}(G) \).

If \( |G| \leq 2 \), then \( \mathcal{B}(G) \) is half-factorial by Proposition 3.12 whence the sets \( \mathcal{V}_k(G) \) are singletons for all \( k \in \mathbb{N} \). Let \( |G| \geq 3 \) and \( k \in \mathbb{N} \). First, we point out that it suffices to prove that \( [k, \rho_k(G)] \subseteq \mathcal{V}_k(G) \). Indeed, suppose that this is done, and let \( l \in [\lambda_k(G), k] \). Then \( l \leq k \leq \rho_l(G) \), hence \( k \in \mathcal{V}_l(G) \) and consequently \( l \in \mathcal{V}_k(G) \).

Thus let \( l \in [k, \rho_k(G)] \) be minimal such that \([l, \rho_k(G)] \subseteq \mathcal{V}_k(G) \) and assume to the contrary that \( l > k \). Let \( \Omega \) be the set of all \( A \in \mathcal{B}(G) \) such that \( \{k, j\} \subseteq \mathcal{L}(A) \) for some \( j \geq l \), and let \( B \in \Omega \) be such that \([B]\)
is minimal. Then $B = U_1 \cdots U_k = V_1 \cdots V_j$, where $j \geq l$ and $U_1, \ldots, U_k, V_1, \ldots, V_j \in \mathcal{A}(G)$. Since $j > k$, we have $B \neq \emptyset[4]$, and (after renumbering if necessary) we may assume that $U_k = g_1 g_2 U'$ and $V_j = g_2 V'$, where $g_1, g_2 \in G$ and $U', V' \in \mathcal{F}(G)$. Then $U'_k = (g_1 + g_2)U' \in \mathcal{A}(G)$, and we suppose that $V_j = (g_1 + g_2) V = W_1 \cdots W_l$, where $t \in \mathbb{N}$ and $W_1, \ldots, W_l \in \mathcal{A}(G)$. If $B' = U_1 \cdots U_{k-1} U'_k$, then $|B'| < |B|$ and $B' = V_1 \cdots V_{j-2} W_1 \cdots W_l$. By the minimal choice of $|B|$, it follows that $j - 2 + t < l$, hence $t = 1, j = l$ and $l - 1 \in \mathcal{V}_k(G)$, a contradiction.

The structure of unions of sets of lengths in much more general settings is studied in [53]. Here we stick to Krull monoids and determine the $\lambda_k(H)$-invariants with respect to the $\rho_k(H)$-invariants.

**Corollary 5.4.** Let $H$ be a Krull monoid with class group $G$ such that every class contains a prime, and suppose that $|G| > 1$. Then for every $l \in \mathbb{N}_0$ we have

$$
\lambda_{ID(G)+j}(H) = \begin{cases} 
2l & \text{for } j = 0 \\
2l + 1 & \text{for } j \in [1, \rho_{2l+1}(G) - ID(G)] \\
2l + 2 & \text{for } j \in [\rho_{2l+1}(G) - ID(G) + 1, D(G) - 1],
\end{cases}
$$

provided that $ID(G) + j \geq 1$.

**Proof.** By Theorem 3.16, it suffices to consider the block monoid $B(G)$. If $|G| = 2$, then $B(G)$ is half-factorial, $D(G) = 2$ and hence the assertion follows. Suppose that $|G| \geq 3$, and thus we get $D(G) \geq 3$.

Let $l \in \mathbb{N}_0$ and $j \in [0, D(G) - 1]$ such that $ID(G) + j \geq 1$. For $j = 0$ the assertion follows from Theorem 4.11.4. Let $j \in [1, D(G) - 1]$. By Theorem 4.11.4 we obtain that

$$
2l + \frac{2j}{D(G)} = \frac{ID(G) + j}{\rho(G)} \leq \lambda_{ID(G)+j}(G) \leq 2l + j.
$$

Thus the assertion follows for $j = 1$, and hence from now on we may suppose that $j \geq 2$. Lemma 4.12.1 implies that $\{2, j\} \subseteq L(B)$ for some $B \in B(G)$ and thus $\lambda_j(G) = 2$. Hence we obtain

$$
\lambda_{ID(G)+j}(G) \leq \lambda_{ID(G)+j}(G) + \lambda_j(G) = 2l + 2,
$$

and therefore $\lambda_{ID(G)+j}(G) \in \{2l + 1, 2l + 2\}$.

If $j \in [2, \rho_{2l+1}(G) - ID(G)]$, then $l \geq 1$ and $ID(G) + j \in V_{2l+1}(G)$ by Theorem 5.3. Thus $\lambda_{ID(G)+j}(G) \leq 2l + 1$ and hence $\lambda_{ID(G)+j}(G) = 2l + 1$.

If $j > \rho_{2l+1}(G) - ID(G)$, then $ID(G) + j > \rho_{2l+1}(G)$ and $ID(G) + j \notin V_{2l+1}(G)$. Thus $\lambda_{ID(G)+j}(G) > 2l + 1$ and hence $\lambda_{ID(G)+j}(G) = 2l + 2$.

**Corollary 5.5.** Let $H$ be a Krull monoid whose class group $G$ is an elementary 2-group and suppose that every class contains a prime. Then for every $k \in \mathbb{N} \geq 2$ and every $l \in \mathbb{N}_0$ we have $V_k(H) = [\lambda_k(H), \rho_k(H)]$,

$$
\rho_k(H) = \left\lfloor \frac{kD(G)}{2} \right\rfloor \quad \text{and} \quad \lambda_{ID(G)+j}(H) = \begin{cases} 
2l + j & \text{for } j \in [0, 1] \\
2l + 1 & \text{for } j \in [2, D(G)/2] \text{ and } l \geq 1, \\
2l + 2 & \text{for } j \in [2, D(G) - 1] \text{ and (either } j > D(G)/2 \text{ or } l = 0),
\end{cases}
$$

provided that $ID(G) + j \geq 1$.

**Proof.** By Theorem 3.16 it suffices to consider the block monoid $B(G)$. By Theorem 5.3 we obtain that $V_k(H) = [\lambda_k(H), \rho_k(H)]$. If $|G| = 2$, then $B(G)$ is half-factorial by Proposition 3.12 whence for all $k \in \mathbb{N}$ we have $\lambda_k(G) = k = \rho_k(G)$.

Now suppose that $|G| \geq 4$ and hence $D(G) > 2$. We first prove the assertion on $\rho_k(G)$ and then the assertion on $\lambda_{ID(G)+j}(G)$.
1. Let $k \in \mathbb{N}$. If $k$ is even, then the assertion follows from Theorem 4.11.3. Suppose we know that
\[ (s) \quad \rho_2(G) \geq \left[ \frac{3D(G)}{2} \right]. \]
Then Theorem 4.11 and Lemma 5.2 imply that
\[ \left[ \frac{3D(G)}{2} \right] + kD(G) \leq \rho_2(G) + \rho_{2k}(G) \leq \left[ \frac{(2k + 3)D(G)}{2} \right] = \left[ \frac{3D(G)}{2} \right] + kD(G), \]
and hence the assertion follows. Thus it remains to prove (s). We pick a basis $(e_1, \ldots, e_{r(G)})$ of $G$ and set $e_0 = e_1 + \ldots + e_{r(G)}$.

First suppose that $r(G) = 2s + 1$ with $s \in \mathbb{N}$. Then
\[
U = e_1 \ldots e_{s+1} e_{s+2} \ldots e_{2s+1} e_0, \quad V = e_1 \ldots e_{s+1} (e_1 + e_{s+2}) \ldots (e_s + e_{2s+1}) (e_{s+1} + \ldots + e_{2s+1}) \quad \text{and}
\]
\[
W = e_{s+2} \ldots e_{2s+1} e_0 (e_1 + e_{s+2}) \ldots (e_s + e_{2s+1}) (e_{s+1} + \ldots + e_{2s+1})
\]
are minimal zero-sum sequences of length $D(G) = 2s + 2$. By construction, $UVW$ may be written as a product of $3D(G)/2$ minimal zero-sum sequences, and hence (s) follows.

Second suppose that $r(G) = 2s$ with $s \in \mathbb{N}$. Then
\[
U = e_1 \ldots e_s e_{s+1} \ldots e_{2s} e_0, \quad V = e_1 \ldots e_s (e_1 + e_{s+1}) \ldots (e_s + e_{2s}) (e_{s+1} + \ldots + e_{2s}) \quad \text{and}
\]
\[
W = e_{s+1} \ldots e_{2s} (e_1 + e_{s+1}) \ldots (e_s + e_{2s}) (e_{s+1} + \ldots + e_{2s})
\]
are minimal zero-sum sequences of length $D(G) = 2s + 1$. By construction, $UVW$ may be written as a product of $3D(G)/2 = 3s + 1$ minimal zero-sum sequences, and hence (s) follows.

2. Since $\rho_k(G) = \left[ \frac{kD(G)}{2} \right]$, the assertion on $\lambda_{D(G)+j}(G)$ follows from Corollary 5.4. \hfill \Box

5.5 Almost arithmetical multiprogressions and the structure of sets of lengths

We start with four simple examples which show the variety of possible structures for sets of lengths.

**Examples 5.6.**

1. **Arithmetical progressions.** Let $d \in \mathbb{N}$. Let $g \in G$ with $\text{ord}(g) = d + 2$, and set $B = (-g)^{d+2} g^{d+2}$. Then for every $l \in \mathbb{N}$ we obviously have
\[
L(B^l) = 2l + \{vl \mid v \in [0, l] \} \in L(G),
\]
whence $L(G)$ contains arithmetical progressions with difference $d$ and any length $l$.

2. **Multidimensional arithmetical progressions.** Let $r \in \mathbb{N}$, $d_1, \ldots, d_r \in \mathbb{N}$ and $l_1, \ldots, l_r \in \mathbb{N}$. For every $i \in [1, r]$, let $G_i$ be a finite abelian group and $B_i^l \in \mathcal{B}(G_i)$ as in 1, such that $L(B_i^l)$ is an arithmetical progression with difference $d_i$ and length $l_i$. If $G_1 \oplus \ldots \oplus G_r \subset G$ and $B = B_1^{l_1} \cdots B_r^{l_r}$, then
\[
L(B) = \sum_{i=1}^{r} L(B_i) \in L(G)
\]
is an $r$-dimensional arithmetical progression.

3. **Arithmetical progressions with gaps at their end.** Let $n \geq 2$, $e_1, e_2 \in G$ independent elements with $\text{ord}(e_1) = 2$, $\text{ord}(e_2) = 2n$ and set $e_0 = e_1 + ne_2$. If $G_0 = \{e_0, e_1, e_2, -e_2\}$ and $U = e_0 e_1 e_2^2$, then
\[
\mathcal{A}(G_0) = \{g^{\text{ord}(g)} \mid g \in G_0\} \cup \{((-e_2)e_2, U, -U)\}.
\]
For every $l \in \mathbb{N}$ we consider
\[
B_l = e_0^2 e_1^2 ((-e_2)_e_2)^{l+2n}.
\]
Let $B_l = A_1 \cdots A_k$ with $A_1, \ldots, A_k \in \mathcal{A}(G_0)$, and let $I \subset \{1, k\}$ be the set of all $i \in \{1, k\}$ such that $supp(A_i) \cap \{e_0, e_1\} \neq \emptyset$. Then $|I| = 2$, say $I = \{1, 2\}$, and we set $C_l = \prod_{i=1}^{k} A_i$. There are the following four possibilities:

- $\{A_1, A_2\} = \{e_0^2, e_1^2\}$. Then $C_l = ((-e_2)e_2)^{n+2l}$ and $L(C_l) = n + 2l + \{\nu(2n - 2) \mid \nu \in [0, l]\}$.
- $\{A_1, A_2\} = \{-U, U\}$. Then $C_l = ((-e_2)e_2)^{n+2l}$ and $L(C_l) = 2l + \{\nu(2n - 2) \mid \nu \in [0, l]\}$.
- $\{A_1, A_2\} = \{U\}$. Then $C_l = ((-e_2)^2e_2)((-e_2)e_2)^{n+2n(l-1)}$ and $L(C_l) = 1 + n + 2l(l - 1) + \{\nu(2n - 2) \mid \nu \in [0, l - 1]\}$.
- $\{A_1, A_2\} = \{-U\}$. Then $C_l = e_2^n((-e_2)e_2)^{n+2n(l-1)}$ and $L(C_l) = 1 + n + 2l(l - 1) + \{\nu(2n - 2) \mid \nu \in [0, l - 1]\}$.

Thus we obtain that

$$L(B_l) = 2 + 2l + \{(D + (2n - 2)Z) \cap [0, 2n - 2l] \cup (n + (2n - 2l))\},$$

where $D = \{0, n - 1, n, 2n - 2\}$. In terms of the following definition, $L(B_l)$ is an AAMP with difference $2n - 2$, period $D$, length $l$ and bound $n$. If in particular $n = 2$, then $L(B_l)$ is an arithmetical progression with difference 2 and a gap at its end.

4. Arithmetical multiprogressions. It can be shown that for every finite subset $L \subset \mathbb{N}_{\geq 2}$ there is a finite abelian group $G_1$ such that $L \in \mathcal{L}(G_1)$ [71, Proposition 4.8.3], say $L = \mathcal{L}(B_1) = x + D$ where $x = \min L$, $\min D = 0$, $\max D = d$ and $B_1 \in \mathcal{B}(G_1)$. By 1., there is a group $G_2$ and a $B_2 \in \mathcal{B}(G_2)$ such that, for every $l \in \mathbb{N}$, $L(B_l^2) = 2l + \{vd \mid \nu \in [0, l]\}$ is an arithmetical progression with difference $d$ and length $l$. Thus for every $l \in \mathbb{N}$ we have

$$L(B_1B_l^2) = L(B_1) + L(B_l^2) = (x + 2l) + D + \{vd \mid \nu \in [0, l]\} = \min L(B_1B_l^2) + (D + d\mathbb{Z} \cap [0, \max L(B_1B_l^2) - \min L(B_1B_l^2)])$$

Definition 5.7. Let $d \in \mathbb{N}$, $l, M \in \mathbb{N}_0$ and $\{0, d\} \subset D \subset [0, d]$. A subset $L \subset \mathbb{Z}$ is called an

- arithmetical multiprogression (AMP for short) with difference $d$, period $D$ and length $l$, if $L$ is an interval of $\min L + D + d\mathbb{Z}$ (this means that $L$ is finite nonempty and $L = (\min L + D + d\mathbb{Z}) \cap [\min L, \max L]$, and $l$ is maximal such that $\min L + ld \in L)$.

- almost arithmetical multiprogression (AAMP for short) with difference $d$, period $D$, length $l$ and bound $M$, if $L = y + (L' \cup L^* \cup L'') \subset y + D + d\mathbb{Z}$ where $L^*$ is an AMP with difference $d$ (whence $L^* \neq \emptyset$), period $D$ and length $l$ such that $\min L^* = 0$, $L' \subset [-M, -1]$, $L'' \subset \max L^* + [1, M]$ and $y \in \mathbb{Z}$.

We call $y + L'$ the initial part, $y + L^*$ the central part and $y + L''$ the end part of $L$.

- almost arithmetical progression (AAP for short) with difference $d$, bound $M$ and length $l$, if it is an AAMP with difference $d$, period $\{0, d\}$, bound $M$ and length $l$.

Note that

- AMPs, AAMPs and AAPs are finite nonempty subsets of $\mathbb{Z}$.
A set $L$ is an AMP if and only if it is an AAMP with bound 0, and it is an arithmetical progression with difference $d$ if and only if it is an AAP with difference $d$ and bound 0.

A set $L$ is an AAMP if and only if the shifted set $y + L$ is an AAMP for any $y \in \mathbb{Z}$.

$L^* = (D + d\mathbb{Z}) \cap [0, \max L^*]$.

AAMPs, as defined above, were introduced in [38], and a slightly less restrictive notion was first defined in [67].

**Definition 5.8.** We say that the Structure Theorem for Sets of Lengths holds for the monoid $H$ if $H$ is atomic and there exist some $M^* \in \mathbb{N}_0$ and a finite nonempty set $\Delta^* \subseteq \mathbb{N}$ such that every $L \in \mathcal{L}(H)$ is an AAMP with some difference $d \in \Delta^*$ and bound $M^*$.

If the Structure Theorem for Sets of Lengths holds for the monoid $H$, then $H$ is a BF-monoid with finite set of distances $\Delta(H)$ (note that the formulation in [71, Definition 4.7.1] is slightly different and erroneous, since it was forgotten to require $\Delta^*(H)$ to be finite). We cite three key results on the structure of sets of lengths in Krull monoids (proofs can be found in [71, Section 4.7], [121] and [71, Theorem 7.6.9]).

**Theorem 5.9.** Let $H$ be a Krull monoid with finite class group $G$. Then the Structure Theorem for Sets of Lengths holds. Moreover, if $|G| \geq 3$ and every class contains a prime, then it holds with the set $\Delta^* = \{ \min \Delta(G_0) | G_0 \subseteq G \text{ with } \Delta(G_0) \neq \emptyset \} \subseteq \Delta(G)$.

**Idea of the Proof.** The proof splits into an abstract additive part and an ideal-theoretic part. Both steps are based on the concepts of Pattern ideals and of Tamely generated ideals which are defined as follows:

- For a finite nonempty set $A \subseteq \mathbb{Z}$ the pattern ideal $\Phi(A)$ is the set of all $a \in H$ for which there is some $y \in \mathbb{Z}$ such that $y + A \subseteq L(a)$.
- A subset $a \subseteq H$ is called tamely generated if there exist a subset $E \subseteq a$ and a bound $N \in \mathbb{N}$ with the following property:
  
  For every $a \in a$ there exists some $e \in E$ such that $e | a$, $\sup e \leq N$ and $t(a, Z(e)) \leq N$.

In the additive part one proves that the Structure Theorem for Sets of Lengths holds for every BF-monoid $H$ with finite set $\Delta(H)$ in which all pattern ideals are tamely generated. This is done in the spirit of additive number theory. To apply this additive result to a BF-monoid $H$, it must be proved that $\Delta(H)$ is finite and that all pattern ideals are tamely generated. This is fairly simple for finitely generated monoids (but far from being simple for C-monoids).

Let $H$ be a Krull monoid as above and let $G_0 \subseteq G$ denote the set of classes containing primes. By Theorem 3.16 it suffices to prove the Structure Theorem for the monoid $\mathcal{B}(G_0)$ of zero-sum sequences over $G_0$. Since $\mathcal{B}(G_0)$ is finitely generated by Proposition 3.12, the assertion follows.

Theorem 5.9 was recently generalized to Krull monoids with finite Davenport constant ([60]). More classes of monoids and domains where the Structure Theorem for Sets of Lengths holds can be found in [71, Section 4.7]. The next theorem is a realization result stating that Theorem 5.9 is sharp.

**Theorem 5.10.** Let $M \in \mathbb{N}_0$ and $\Delta^* \subseteq \mathbb{N}$ be a finite nonempty set. Then there exists a Krull monoid $H$ with finite class group such that the following holds: for every AAMP $L$ with difference $d \in \Delta^*$ and bound $M$ there is some $y_{H,L} \in \mathbb{N}$ such that

$$y + L \in \mathcal{L}(H) \quad \text{for all} \quad y \geq y_{H,L}.$$ 

Indeed, there exists an algebraic number field such that its ring of integers has this property.
The next result is in a certain contrast to the previous two. In terms of zero-sum sequences it states that whenever the underlying set supp(\(S\)) of a given zero-sum sequence \(S\) is a group, then the factorizations of \(S\) are as nice as possible. Indeed, its catenary degree \(c(\(S\))\) is bounded above by 3, and its set of lengths \(L(\(S\))\) is an arithmetical progression with difference 1.

**Theorem 5.11.** Let \(H\) be a Krull monoid with class group \(G\) and \(a \in H\) such that 
\[
\text{supp}(\beta(a)) \cup \{0\} \subseteq G
\]
is a subgroup. Then \(c(a) \leq 3\) and hence the set of lengths \(L(a)\) is an arithmetical progression with difference 1.

The main tool in the proof of Theorem 5.11 is the following result on the structure of additively closed sequences (see [50] and [71, Theorem 7.5.2]).

**Proposition 5.12.** Let \(S, B, C \in \mathcal{F}(G^*)\) be sequences such that \(S = BC\), \(|S| \geq 4\) and \(|B| \geq |C|\). Suppose that, for all \(g_1, g_2 \in G\),
\[
\text{if } g_1g_2|B \text{ or } g_1g_2|C, \text{ then } (g_1 + g_2)|S.
\]
Then \(S\) has a proper zero-sum subsequence, apart from the following exceptions:

1. \(|C| = 1, \text{ and we are in one of the following cases:}\)
   - \(B = g^k\) and \(C = 2g\) for some \(k \geq 3\) and \(g \in G\) with \(\text{ord}(g) \geq k + 2\).
   - \(B = g^k(2g)\) and \(C = 3g\) for some \(k \geq 2\) and \(g \in G\) with \(\text{ord}(g) \geq k + 5\).
   - \(B = g_1g_2(g_1 + g_2)\) and \(C = g_1 + 2g_2\) for some \(g_1, g_2 \in G\) with \(\text{ord}(g_1) = 2\) and \(\text{ord}(g_2) \geq 5\).
2. \(\{B, C\} = \{g(9g)(10g), (11g)(3g)(14g)\}\) for some \(g \in G\) with \(\text{ord}(g) = 16\).

Theorem 5.11 and some analytic machinery are the main ingredients to obtain the following density result (see [71, Theorem 9.4.11]). It states that the factorizations and hence the sets of lengths of "almost all" elements in a ring of integers are "as nice as possible".

**Corollary 5.13.** Let \(K\) be an algebraic number field with ring of integers \(R\) and ideal class group \(G\), and let \(H = \{aR \mid a \in R^*\}\) denote the monoid of non-zero principal ideals. For a principal ideal \(a \in H\) let \(|a| = (R:a)\) denote its norm. Then for every \(x \geq 2\) we have
\[
\frac{|\{a \in H \mid c(a) \leq 3, |a| \leq x\}|}{|\{a \in H \mid |a| \leq x\}|} = 1 + O((\log x)^{-1/|G|}).
\]

5.C The characterization problem

Two reduced Krull monoids \(H\) and \(H'\) are isomorphic if and only if there is a group isomorphism \(\Phi: \mathcal{C}(H) \to \mathcal{C}(H')\) such that for every class \(g \in \mathcal{C}(H)\) the number of primes in \(g\) equals the number of primes in the class \(\Phi(g) \in \mathcal{C}(H')\) (see [71, Theorem 2.5.4]). If \(H\) is the multiplicative monoid of the ring of integers of an algebraic number field, then the class group is finite and the set of primes in each class is denumerable. Thus the traditional idea in algebraic number theory, that the class group determines the arithmetic, is justified. Initiated by a problem of W. Narkiewicz in the 1970s, a huge variety of explicit results in this direction was derived.

If the class group of a Krull monoid \(H\) is finite and every class contains a prime, then, roughly speaking, the system of sets of factorizations \(\mathcal{Z}(H) = \{Z(a) \mid a \in H\}\) determines the class group (see [71, Sections 7.1 and 7.2]). The question arises, which is still wide open, whether the same is true for the system of sets of lengths. Clearly, if \(H\) and \(H'\) are reduced Krull monoids with isomorphic class groups \(G, G'\) and primes in all classes, then
\[
\mathcal{L}(H) = \mathcal{L}(G) = \mathcal{L}(H')
\]
but $H$ and $H'$ need not be isomorphic. By Proposition 3.12.4 it follows that
\[ \mathcal{L}(C_1) = \{ \{ k \} \mid k \in \mathbb{N}_0 \} = \mathcal{L}(C_2), \]
and it is easy to check (details may be found in [71, Theorem 7.3.2]) that
\[ \mathcal{L}(C_3) = \{ y + 2k + [0,k] \mid y, k \in \mathbb{N}_0 \} = \mathcal{L}(C_2 \oplus C_2). \]
Note that $\mathcal{D}(C_3) = \mathcal{D}(C_2 \oplus C_2) = 3$, and $C_1, C_2, C_2 \oplus C_2$ and $C_3$ are the only finite abelian groups $G'$
with $\mathcal{D}(G') \leq 3$. So the best we can hope for is a positive answer to the following question:

Given two finite abelian groups $G$ and $G'$ with $\mathcal{D}(G) \geq 4$ such that $\mathcal{L}(G) = \mathcal{L}(G')$. Does it follow that $G \cong G'$?

Up to now there is known no pair of non-isomorphic groups $(G, G')$ with $\mathcal{D}(G) \geq 4$ and $\mathcal{L}(G) = \mathcal{L}(G')$. We start with some simple observations and then we gather the results known so far.

**Proposition 5.14.**

1. $\mathcal{L}(G) = \{ y + L \mid y \in \mathbb{N}_0, L \in \mathcal{L}(G^*) \} \supset \{ \{ y \} \mid y \in \mathbb{N}_0 \}$, and equality holds if and only if $|G| \leq 2$.
2. If $G_0 \subset G$ is a subset, then $\mathcal{L}(G_0) \subset \mathcal{L}(G)$.
3. Let $G'$ be an abelian group with $|G'| \geq 3$ such that $\mathcal{L}(G) = \mathcal{L}(G')$. Then we have $\rho_k(G) = \rho_k(G')$ and $\lambda_k(G) = \lambda_k(G')$ for every $k \in \mathbb{N}$, $\mathcal{D}(G) = \mathcal{D}(G')$ and $\Delta(G) = \Delta(G')$.
4. If $G'$ is an abelian group with $|G'| \geq 3$, then it follows that $\mathcal{L}(G) = \mathcal{L}(G')$.

**Proof.**

1. Observe that $\mathcal{B}(G) = \{ 0^y B \mid B \in \mathcal{B}(G^*), y \in \mathbb{N}_0 \}$, and if $B \in \mathcal{B}(G^*)$ and $y \in \mathbb{N}_0$, then $L(0^y B) = y + L(B)$. By definition, we have $|L| = 1$ for every $L \in \mathcal{L}(G)$ if and only if $\mathcal{B}(G)$ is half-factorial, and by Proposition 3.12 this is equivalent to $|G| \leq 2$.
2. Obvious.
3. By 1. we obtain $|G| \geq 3$. By the very definition we have $\Delta(G) = \Delta(G')$, $\lambda_k(G) = \lambda_k(G')$ and $\rho_k(G) = \rho_k(G')$ for every $k \in \mathbb{N}$, and hence $\mathcal{D}(G) = \mathcal{D}(G')$ by Theorem 4.11.3.
4. If $G'$ is an abelian group with $\mathcal{L}(G) = \mathcal{L}(G')$ and $|G'| \geq 3$, then it follows that $\mathcal{D}(G) = \mathcal{D}(G') \geq 1 + d^*(G')$ (see Lemma 4.3.2). By the very definition of $d^*(\cdot)$, there are up to isomorphisms only finitely many finite abelian groups $G'$ with $d^*(G') < \mathcal{D}(G)$. □

**Proposition 5.15.** Let $G'$ be a finite abelian group with $\mathcal{D}(G') \in [4, 10]$. If $\mathcal{L}(G) = \mathcal{L}(G')$, then $G \cong G'$.

**Theorem 5.16.** Let $G$ be a finite elementary $p$-group and let $G'$ be a finite elementary $q$-group with $\mathcal{D}(G') \geq 4$ and with primes $p, q \in \mathbb{P}$. If $\mathcal{L}(G) = \mathcal{L}(G')$, then $G \cong G'$.

**Theorem 5.17.** Let $G'$ be a finite abelian group with $\mathcal{D}(G') \geq 4$ and suppose that one of the following statements hold:

1. $G$ is cyclic.
2. $G$ is an elementary 2-group.
3. $G \cong C_2 \oplus C_{2n}$ with $n \geq 3$.
4. $G \cong C_2 \oplus C_n$ with $n \geq 3$.

If $\mathcal{L}(G) = \mathcal{L}(G')$, then $G \cong G'$. 
The results given in 5.15, 5.16 and 5.17 are mainly due to Wolfgang A. Schmid (see [122, 124, 119] and [71, Section 7.3]). They are based on solid investigations of the set $\Delta^*(G) = \{ \min \Delta(G_0) \mid G_0 \subset G \text{ with } \Delta(G_0) \neq \emptyset \}$, which occurs in Theorem 5.9. We do not discuss these topics here, but using results on the $\rho_k(G)$-invariants we will be able prove Theorem 5.17 for cyclic groups and for elementary 2-groups (see Corollary 7.28).

6. Addition theorems and direct zero-sum problems

We start with the classical theorems of Kneser and Kemperman-Scherk which are fundamental in additive group theory. Having these results at our disposal we continue the investigation of the Davenport constant, of the Erdős-Ginzburg-Ziv constant and of related invariants in zero-sum theory.

6.A The Theorems of Kneser and of Kemperman-Scherk

Let $k \in \mathbb{N}$ and $A, B, A_1, \ldots, A_k \subset G$ be nonempty subsets. Then

$$\text{Stab}(A) = \{ g \in G \mid g + A = A \}$$

denotes the stabilizer of $A$, which is a subgroup of $A$. For $g \in G$, let

$$r_{A_1, \ldots, A_k}(g) = \left| \left\{ (a_1, \ldots, a_k) \in A_1 \times \ldots \times A_k \mid g = a_1 + \ldots + a_k \right\} \right|$$

denote the number of representations of $g$ as a sum of elements of $A_1, \ldots, A_k$. In particular, we have

$$r_{A, B}(g) = \left| \left\{ (a, b) \in A \times B \mid g = a + b \right\} \right| = |A \cap (g - B)|.$$

In the 1950s M. Kneser proved the following addition theorem formulated in Theorem 6.1. Since a proof is given in the Part "Sumsets and Structure" by Imre Z. Ruzsa, we do not give a proof here. Moreover, a variety of proofs and historical references may be found in each of the following monographs [104, Chapter 1], [107, Chapter 4], [71, Section 5.2], and [130, Theorem 5.5]. For some recent development around Kneser's Theorem, and in particular on the isoperimetric approach, we refer to [22, 83, 126, 97, 19, 81, 25, 24, 3, 89, 90, 93, 91, 80].

Theorem 6.2 was first proved by J.H.B. Kemperman ([98]; the special case $\min \{ r_{A, B}(g) \mid g \in A + B \} = 1$ was settled before by P. Scherk answering a question of L. Moser [118]; a short proof of Scherk’s Theorem, which is not based on Kneser’s Theorem, may be found in [90]). Corollary 6.3 is crucial in many investigations on the structure of zero-sum free sequences (as for example in the proofs of Proposition 6.9 and Corollary 7.10).

Theorem 6.1 (Kneser). Let $K = \text{Stab}(A + B)$ be the stabilizer of $A + B$.

1. There exists a subgroup $K' \subset K$ such that $|A + B| \geq |A| + |B| - |K'|$.
2. There exists a subgroup $K' \subset K$ such that $|A + B| \geq |A + K'| + |B + K'| - |K'|$.
4. Either $|A + B| \geq |A| + |B|$ or $|A + B| = |A + K| + |B + K| - |K|$.

Theorem 6.2 (Kemperman-Scherk). Let $K = \text{Stab}(A + B)$ be the stabilizer of $A + B$. Then

$$|A + B| \geq |A| + |B| - \min \{ r_{(a + K) \cap A, (b + K) \cap B}(g) \mid a \in A, b \in B, g \in a + b + K \} \geq |A| + |B| - \min \{ r_{A, B}(g) \mid g \in A + B \}.$$
Corollary 6.3. Let $k \in \mathbb{N}$.

1. Let $A_1, \ldots, A_k \subseteq G$ be nonempty subsets. Then

$$|A_1 + \ldots + A_k| \geq |A_1| + \ldots + |A_k| - (k - 2) - \min \{r_{A_1,\ldots,A_k}(g) \mid g \in A_1 + \ldots + A_k\}.$$  

2. If $S = S_1 \cdot \ldots \cdot S_k \subseteq A^*(G)$, then

$$|\Sigma(S)| \geq |\Sigma(S_1)| + \ldots + |\Sigma(S_k)|.$$  

Proof. 1. We proceed by induction on $k$. For $k = 1$ the assertion is clear. Suppose that $k \geq 2$. We start with the following assertion.

A. For every $g \in A_1 + \ldots + A_k$ we have

$$r_{A_1,\ldots,A_k}(g) \geq \min \{r_{A_1,\ldots,A_k}(a) \mid a \in A_1 + \ldots + A_{k-1}\} + \min \{r_{A_1,\ldots,A_k}(b) \mid b \in A_1 + \ldots + A_k\} - 1.$$  

Proof of A. If $g \in A_1 + \ldots + A_k$, then we get

$$r_{A_1,\ldots,A_k}(g) \geq \min \{r_{A_1,\ldots,A_k}(a) \mid a \in A_1 + \ldots + A_{k-1}\} \cdot r_{A_1,\ldots,A_k}(g)$$

$$\geq \min \{r_{A_1,\ldots,A_k}(a) \mid a \in A_1 + \ldots + A_{k-1}\} \cdot \min \{r_{A_1,\ldots,A_k}(b) \mid b \in A_1 + \ldots + A_k\}$$

$$\geq \min \{r_{A_1,\ldots,A_k}(a) \mid a \in A_1 + \ldots + A_{k-1}\} + \min \{r_{A_1,\ldots,A_k}(b) \mid b \in A_1 + \ldots + A_k\} - 1.$$  

Now the induction hypothesis, Theorem 6.2 and A imply that

$$|A_1 + \ldots + A_k| \geq |A_1 + \ldots + A_{k-1}| + |A_k| - \min \{r_{A_1,\ldots,A_k}(b) \mid b \in A_1 + \ldots + A_k\}$$

$$\geq |A_1| + \ldots + |A_{k-1}| + |A_k| - (k - 3) - \min \{r_{A_1,\ldots,A_k}(a) \mid a \in A_1 + \ldots + A_{k-1}\} + |A_k| - \min \{r_{A_1,\ldots,A_k}(b) \mid b \in A_1 + \ldots + A_k\}$$

$$\geq |A_1| + \ldots + |A_k| - (k - 2) - \min \{r_{A_1,\ldots,A_k}(g) \mid g \in A_1 + \ldots + A_k\}.$$  

2. For $i \in [1, k]$ we set $A_i = \Sigma(S_i) \cup \{0\}$. Then $r_{A_1,\ldots,A_k}(0) = 1$, and hence 1. implies that

$$|\Sigma(S)| \geq |A_1 + \ldots + A_k| - 1 \geq |A_1| + \ldots + |A_k| - k = |\Sigma(S_1)| + \ldots + |\Sigma(S_k)|.$$  

6.B On the Erdős-Ginzburg-Ziv constant $s(G)$ and on some of its variants
Definition 6.4. Let \( \exp(G) = n \).

1. A sequence \( S \in \mathcal{F}(G) \) is called short (in \( G \)) if \( |S| \in [1, n] \).

2. We denote by \( \eta(G) \) the smallest integer \( l \in \mathbb{N} \) with the following property:
   - Every sequence \( S \in \mathcal{F}(G) \) of length \( |S| \geq l \) has a short zero-sum subsequence.

3. We denote by \( s(G) \) the smallest integer \( l \in \mathbb{N} \) with the following property:
   - Every sequence \( S \in \mathcal{F}(G) \) of length \( |S| \geq l \) has a zero-sum subsequence \( T \) of length \( |T| = n \).

The invariant \( s(G) \) will be called the Erdős-Ginzburg-Ziv constant (EGZ constant for short).

4. We denote by \( s_n(G) \) the smallest integer \( l \in \mathbb{N} \) with the following property:
   - Every sequence \( S \in \mathcal{F}(G) \) of length \( |S| \geq l \) has a nontrivial zero-sum subsequence \( T \) of length \( |T| = 0 \mod n \).

The investigation of these invariants has a long tradition in combinatorial number theory as well as in finite geometry. Indeed, the Erdős-Ginzburg-Ziv Theorem, first proved in 1961 ([32]) and stating that \( s(C_n) = 2n - 1 \) (see Corollary 6.11), is considered as a starting point in zero-sum theory. As already pointed out by H. Harborth ([94]), \( s(C_n^r) \) is the smallest integer \( l \in \mathbb{N} \) such that every set of \( l \) lattice points in an \( r \)-dimensional euclidean space contains \( n \) elements which have a centroid with integral coordinates. Moreover, if \( \varphi \) is the maximal size of a cap in \( AG(r, 3) \), then \( s(C_3^r) = 2\varphi + 1 \) (see [28, Section 5] for the connection to finite geometry).

The invariant \( \eta(G) \) is a crucial tool in the inductive method which roughly works as follows: for the investigation of a given sequence \( S \in \mathcal{F}(G) \) proceed in the following three steps:

- Find a suitable subgroup \( K \subset G \) and consider the natural epimorphism \( \varphi : G \to G/K \).
- Consider a factorization \( S = S_0 S_1 \cdots S_k \) such that \( |S_i| \) is small and \( \varphi(S_i) \in B(G/K) \) for all \( i \in [1, k] \).
- Investigate the sequences \( T = \sigma(S_1) \cdots \sigma(S_k) \in \mathcal{F}(K) \) and \( S_0 T \in \mathcal{F}(G) \). Clearly, if \( S \) is zero-sum free, then \( S_0 T \) is zero-sum free too.

The inductive method was already used successfully by J.E. Olson and P. van Emde Boas in the 1960s, and then it was more and more refined by W. Gao and many other authors. After having done the necessary preparations in Lemmas 6.7 and 6.8 we will demonstrate the power of this method in 6.13 and 6.15 (the polynomial method - see the article "The polynomial method in additive combinatorics" by G. Károlyi in Part III - and coverings by cosets - see [71, Chapter 5.6], [128, 102] - are further important methods, which however cannot be discussed here).

Our main result in this subsection is Theorem 6.13 which gives, for groups \( G \) of rank \( r(G) \leq 2 \), the precise values of \( d(G) \), \( \eta(G) \) and \( s(G) \). For \( d(G) \) this was shown independently by J.E. Olson and D. Kruyswijk in the late 1960s. The result on \( s(G) \) is based on C. Reiher's work ([114]). The proof of 6.13, as presented here, follows the lines from [71, Theorem 5.8.3]. On our way we show the Theorem of Erdős-Ginzburg-Ziv (Corollary 6.11; for some recent development in the flavor of Erdős-Ginzburg-Ziv see [40, 39, 82, 84, 86]).

Lemma 6.5.

1. We have \( D(G) \leq \eta(G) \leq s(G) - \exp(G) + 1 \).

2. Let \( G = C_{n_1} \oplus \cdots \oplus C_{n_r} \) with \( r = r(G) \) and \( 1 < n_1 | \ldots | n_r \). If \( r \geq 2 \), then \( \eta(G) \geq d^*(G) + n_1 \).

Proof. 1. The inequality \( D(G) \leq \eta(G) \) follows by Lemma 4.2.3 and the very definition of \( \eta(G) \).

For the proof of the second inequality let \( n = \exp(G) \), and consider a sequence \( S \in \mathcal{F}(G) \) of length \( |S| \geq s(G) - n + 1 \). We must prove that \( S \) has a short zero-sum subsequence. The sequence \( T = 0^{n-1} S \in \mathcal{F}(G) \) satisfies \( |T| \geq s(G) \), and therefore there exists a zero-sum subsequence \( T' = 0^k S' \) of \( T \), where \( k \in [0, n - 1] \), \( S' \) does not contain \( S \) and \( |T'| = |S'| + k = n \). Hence \( S' \) is a short zero-sum subsequence of \( S \).
Let $r \geq 2$ and $(e_1, \ldots, e_r)$ be a basis of $G$ such that $\text{ord}(e_i) = n_i$ for all $i \in [1, r]$.

$$e_0 = \sum_{i=1}^{r} e_i \quad \text{and} \quad S = e_0^{n_i-1} \prod_{i=1}^{r} e_i^{n_i-1} \in \mathcal{F}(G).$$

We assert that $S$ has no short zero-sum subsequence. Let

$$T = e_0^{n_0} \prod_{i=1}^{r} e_i^{n_i'},$$

where $n_0 \in [0, n_1 - 1]$ and $n_i' \in [0, n_i - 1]$ for all $i \in [1, r]$, be a nontrivial zero-sum subsequence of $S$. Then $n_0 \geq 1$ by Lemma 4.3. Since $0 = \sigma(T) = (n_1' + n_0)e_1 + \ldots + (n_r' + n_0)e_r$, it follows that $n_i' + n_0 \equiv 0 \mod n_i$ for all $i \in [1, r]$, and $1 \leq n_i' + n_0 \leq 2n_i - 2$ implies $n_i' = n_i - n_0$ for all $i \in [1, r]$. Hence

$$|T| = n_0 + \sum_{i=1}^{r} (n_i - n_0) = n_r + \sum_{i=1}^{r-1} (n_i - n_0) > n_r = \exp(G),$$

and thus $T$ is not a short zero-sum sequence of $S$ over $G$. \hfill \Box

**Lemma 6.6.** Let $S \in \mathcal{F}(G)$ and $n \geq 2$.

1. If $|S| \geq D(G \oplus C_n)$ and $D(G \oplus C_n) \leq 3n - 1$, then $S$ has a zero-sum subsequence $T \in \mathcal{B}(G)$ of length $|T| \in \{n, 2n\}$.

2. Suppose that $D(G) \leq 2n - 1$, $D(G \oplus C_n) \leq 3n - 1$ and $|S| \geq D(G \oplus C_n)$. Then $S$ has a zero-sum subsequence $T \in \mathcal{B}(G)$ of length $|T| \in [1, n]$. In particular, if $n \leq \exp(G)$, then

$$\eta(G) \leq D(G \oplus C_n).$$

3. If $\exp(G) = n$, then

$$D(G) + n - 1 \leq s_{\text{un}}(G) \leq \min\{s(G), D(G \oplus C_n)\}.$$

**Proof.** Let $G \oplus C_n = G \oplus \langle e \rangle$ with $\text{ord}(e) = n$, so that every $h \in G \oplus C_n$ has a unique representation $h = g + je$, where $g \in G$ and $j \in [0, n - 1]$. We define $\varphi : G \to G \oplus C_n$ by $\varphi(g) = g + e$ for every $g \in G$.

1. Since $\varphi(S) \in \mathcal{F}(G \oplus C_n)$ and $|\varphi(S)| = |S| \geq D(G \oplus C_n)$, $S$ has a subsequence $T$ with $1 \leq |T| \leq D(G \oplus C_n) \leq 3n - 1$ such that $\varphi(T)$ has sum zero. Because $0 = \sigma(\varphi(T)) = \sigma(T) + |T|e \in G \oplus C_n$, we obtain that $\sigma(T) = 0$, $|T| \equiv 0 \mod n$, and $|T| \leq 3n - 1$ implies $|T| \in \{n, 2n\}$.

2. If $|S| \geq D(G \oplus C_n)$, then by 1. there exists a zero-sum subsequence $T$ of $S$ such that $|T| \in \{n, 2n\}$. If $|T| \leq n$, we are done. If $|T| = 2n$, then $|T| \geq D(G)$ implies $T = T_1T_2$ for some zero-sum subsequences $T_1, T_2$ with $1 \leq |T_1| \leq |T_2|$, and $T_1$ is the desired subsequence of $S$.

3. If $S \in \mathcal{F}(G)$ is a zero-sum free sequence of length $|S| = D(G) - 1$, then the sequence $0^{n-1}S$ has no zero-sum subsequence of length divisible by $n$. Thus $D(G) + n - 2 = \left\lceil D(G) \right\rceil < s_{\text{un}}(G)$. By definition we have $s_{\text{un}}(G) \leq s(G)$.

In order to verify that $s_{\text{un}}(G) \leq D(G \oplus C_n)$, let $S = \prod_{i=1}^{l} g_i \in \mathcal{F}(G)$ with $l = D(G \oplus C_n)$. Then the sequence $\prod_{i=1}^{l} (g_i + e) \in \mathcal{F}(G \oplus C_n)$ has a zero-sum subsequence $T$ of length $|T| \equiv 0 \mod n$, and whence the same is true for $S$. \hfill \Box

**Lemma 6.7.** Let $\varphi : G \to \overline{G}$ be a group homomorphism and $k \in \mathbb{N}$.

1. If $S \in \mathcal{F}(G)$ and $|S| \geq (k - 1) \exp(\overline{G}) + s(\overline{G})$, then $S$ admits a product decomposition $S = S_1 \ldots S_k S'$, where $S_1, \ldots, S_k, S' \in \mathcal{F}(G)$ and, for every $i \in [1, k]$, $\varphi(S_i)$ has sum zero and length $|S_i| = \exp(\overline{G})$.

2. If $S \in \mathcal{F}(G)$ and $|S| \geq (k - 1) \exp(\overline{G}) + \eta(\overline{G})$, then $S$ admits a product decomposition $S = S_1 \ldots S_k S'$, where $S_1, \ldots, S_k, S' \in \mathcal{F}(G)$ and, for every $i \in [1, k]$, $\varphi(S_i)$ has sum zero and length $|S_i| \in [1, \exp(\overline{G})]$. 

Proof. 1. Suppose that for some \( j \in [0, k - 1] \) we have found a product decomposition \( S = S_1 \cdots S_j S' \) where \( S_1, \ldots, S_j, S' \) \( \in \mathcal{F}(G) \) and, for every \( i \in [1, j] \), \( \varphi(S_i) \) has sum zero and length \( |S_i| = \exp(K) \). Then
\[
|\varphi(S)| = |S'| = |S| - j \exp(K) \geq (k - 1 - j) \exp(K) + s(G) \geq s(G),
\]
and therefore \( S' \) has a subsequence \( S_{j+1} \) such that \( \varphi(S_{j+1}) \) has sum zero and length \( |S_{j+1}| = \exp(K) \). Now the assertion follows by induction on \( j \).

2. This is proved in precisely the same way as 1. \( \square \)

Lemma 6.8. Let \( K \subset G \) be a subgroup.
1. If \( S \in \mathcal{F}(G) \) and \( |S| \geq (s(K) - 1) \exp(G/K) + s(G/K) \), then \( S \) has a zero-sum subsequence \( T \) of length \( |T| = \exp(K) \exp(G/K) \). In particular, if \( \exp(G) = \exp(K) \exp(G/K) \), then
\[
s(G) \leq (s(K) - 1) \exp(G/K) + s(G/K).
\]
2. If \( S \in \mathcal{F}(G) \) and \( |S| \geq (\eta(K) - 1) \exp(G/K) + \eta(G/K) \), then \( S \) has a zero-sum subsequence \( T \) of length \( 1 \leq |T| \leq \exp(K) \exp(G/K) \). In particular, if \( \exp(G) = \exp(K) \exp(G/K) \), then
\[
\eta(G) \leq (\eta(K) - 1) \exp(K) \exp(G/K).
\]
3. \( d(G) \leq d(K) \exp(G/K) + \max\{d(G/K), \eta(G/K) - \exp(G/K) - 1\} \).

Proof. Let \( \varphi : G \to G/K \) denote the canonical epimorphism. If \( K = \{0\} \), then all assertions are obvious. Suppose that \( K \neq \{0\} \).

1. Let \( S \in \mathcal{F}(G) \) be a sequence with \( |S| \geq (s(K) - 1) \exp(G/K) + s(G/K) \). By Lemma 6.7.1, \( S \) has a product decomposition \( S = S_1 \cdots S_{s(K)} S' \), where \( S_1, \ldots, S_{s(K)}, S' \) \( \in \mathcal{F}(G) \) and, for every \( i \in [1, s(K)] \), \( \varphi(S_i) \) has sum zero and length \( |S_i| = \exp(G/K) \). Then the sequence \( \sigma(S_1) \cdots \sigma(S_{s(K)}) \in \mathcal{F}(K) \) has a zero-sum subsequence \( V \) of length \( |V| = \exp(K) \), say
\[
V = \prod_{i \in J} \sigma(S_i), \text{ where } J \subset [1, s(K)] \text{ and } |J| = \exp(K).
\]
Thus the sequence
\[
T = \bigcap_{i \in J} S_i
\]
is a zero-sum subsequence of \( S \) of length \( |T| = |J| \exp(G/K) = \exp(K) \exp(G/K) \).

2. This is proved in precisely the same way as 1.

3. Let \( S \in \mathcal{F}(G) \) be a sequence of length
\[
|S| > d(K) \exp(G/K) + \max\{d(G/K), \eta(G/K) - \exp(G/K) - 1\}.
\]
We must prove that \( S \) is not zero-sum free. Since \( |S| \geq (d(K) - 1) \exp(G/K) + \eta(G/K) \), Lemma 6.7.2 provides us with a product decomposition \( S = S_1 \cdots S_{d(K)} S' \), where \( S_1, \ldots, S_{d(K)}, S' \) \( \in \mathcal{F}(G) \) and, for every \( i \in [1, d(K)] \), \( \varphi(S_i) \) has sum zero and length \( |S_i| \in [1, \exp(G/K)] \). Now we obtain \( |S'| \geq |S| - \exp(G/K) d(K) > d(K) \), and therefore \( S' \) has a nontrivial subsequence \( S_0 \) such that \( \varphi(S_0) \) has sum zero. Hence \( V = \sigma(S_0) \sigma(S_1) \cdots \sigma(S_{d(K)}) \in \mathcal{F}(K) \), and \( |V| > d(K) \) implies that \( V \) is not zero-sum free. Hence \( T = S_0 S_1 \cdots S_{d(K)} \) is a subsequence of \( S \) which is not zero-sum free. \( \square \)

The following result was found independently by several authors. Its history is described in [92].

Proposition 6.9. Let \( S \in \mathcal{F}(G) \) be a sequence of length \( |S| \geq |G| \) and \( k! = \max\{\text{ord}(g) \mid g \in \text{supp}(S)\} \). Then \( S \) has a nontrivial zero-sum subsequence \( T \) of length \( |T| \leq \min\{h(S), k!\} \).
Proof. We set \( k = h(S) \). If \( k' \leq k \), let \( g \in G \) be such that \( v_g(S) = k \). Then \( T = g^{ord(g)} \) has the desired property. Hence it is sufficient to prove that \( S \) has a zero-sum subsequence of \( T \) of length \([7] \in [1, k]\). If \( 0 \in \text{supp}(S) \), we set \( T = 0 \). Thus suppose that \( 0 \notin \text{supp}(S) \). There exists a decomposition \( S = S_1 \ldots S_k \), where \( S_1, \ldots, S_k \in \mathcal{F}(G) \) are squarefree. For \( i \in [1, k] \), let \( B_i = \text{supp}(S_i) \), \( A_i = B_i \cup \{0\} \), and assume that \( S \) has no zero-sum subsequence as required. This implies that \( r_{A_1, \ldots, A_k}(0) = 1 \), and thus Corollary 6.3 implies that
\[
| A_1 + \ldots + A_k | \geq | A_1 | + \ldots + | A_k | - k + 1 = | B_1 | + \ldots + | B_k | + 1 = | G | + 1,
\]
a contradiction. \( \square \)

Theorem 6.10 (Gao). We have \( \eta(G) \leq | G | \) and \( s(G) \leq | G | + \exp(G) - 1 \).

Proof. The first inequality is an immediate consequence of Proposition 6.9. In order to verify the upper bound for \( s(G) \), we set \( n = \exp(G) \) and must prove that every sequence \( S \in \mathcal{F}(G) \) of length \( | S | \geq | G | + n - 1 \) has a zero-sum subsequence of length \( n \). Thus assume that
\[
S = g_1^{k_1} \ldots g_l^{k_l} \in \mathcal{F}(G),
\]
where \( | S | \geq | G | + n - 1 \), \( k = k_1 \geq \cdots \geq k_l \geq 1 \) and \( g_1, \ldots, g_l \in G \) are distinct. If \( k \geq n \), then \( g_l^n \) is a zero-sum subsequence of length \( n \). Therefore we assume that \( k \leq n - 1 \) and \( l \geq 2 \), and we consider the sequence
\[
U = (g_2 - g_1)^{k_2} \ldots (g_l - g_1)^{k_l} \in \mathcal{F}(G).
\]
It is sufficient to prove that \( U \) has a zero-sum subsequence \( V \) such that \( n - k \leq | V | \leq n \). Indeed, if \( V = (g_2 - g_1)^{k_2} \cdots (g_l - g_1)^{k_l} \) is such a zero-sum subsequence, where \( k_i \in [0, k_i] \) for all \( i \in [2, l] \) and \( n - k \leq k_2 + \ldots + k_l \leq n \), then \( 0 \leq n - (k_2 + \ldots + k_l) \leq k \), and the sequence
\[
T = g_1^{n-(k_2+\ldots+k_l)} g_2^{k_2} \cdots g_l^{k_l}
\]
is a zero-sum subsequence of \( S \) of length \( n \).

Since \( | U | = | S | - k \geq | G | + n - 1 - k \geq | G | \) and \( \eta(G) \leq | G | \), it follows that \( U \) has a short zero-sum subsequence. Let \( V \) be a short zero-sum subsequence of \( U \) of maximal length and assume, contrary to our requirement, that \( | V | \leq n - k - 1 \). If \( U = V V' \), then \( | V' | = | U | - | V | \geq (| G | + n - 1 - k) - (n - k - 1) = | G | \), and by Proposition 6.9 it follows that \( V' \) has a zero-sum subsequence \( V'' \) of length
\[
1 \leq | V'' | \leq \max \{ v_g(V') \mid g \in G \} \leq \max \{ v_g(U) \mid g \in G \} \leq k.
\]
Then \( V V'' \) is a zero-sum subsequence of \( U \) of length
\[
| V | \leq | V V'' | = | V | + | V'' | \leq (n - k - 1) + k = n - 1,
\]
a contradiction to the maximality of \( | V | \). \( \square \)

In the same spirits (using 6.9 and 6.10) W. Gao proved that \( | G | + d(G) \) is the smallest integer \( l \in \mathbb{N} \) such that every sequence \( T \in \mathcal{F}(G) \) of length \( | T | \geq l \) has a zero-sum subsequence of length \( | G | \) (see [42] and [71, Proposition 5.7.9]). There is a weighted generalization of this theorem by Y. ould Hamidoune [92] and for more of this flavor see [66, 1, 84, 78, 85]). For cyclic groups Gao’s Theorem 6.10 reduces to the classical result of Erdős-Ginzburg-Ziv.

Corollary 6.11 (Erdős-Ginzburg-Ziv). For every \( n \in \mathbb{N} \) we have
\[
\eta(C_n) = n \quad \text{and} \quad s(C_n) = 2n - 1.
\]
Proof. By Lemma 6.5 and Theorem 6.10, we obtain
\[ n = D(C_n) \leq \eta(C_n) \leq |C_n| = n \]
and thus \( \eta(C_n) = n \). Again by Lemma 6.5 and by Theorem 6.10 we get
\[ 2n - 1 = \eta(C_n) + \exp(C_n) - 1 \leq s(C_n) \leq |C_n| + \exp(C_n) - 1 = 2n - 1 \]
and thus \( s(C_n) = 2n - 1 \). \( \square \)

**Proposition 6.12 (Reiher).** For every prime \( p \in \mathbb{P} \) we have \( s(C_p \oplus C_p) \leq 4p - 3 \).

Proof. The original proof by C. Reiher (see [114]) is based on the Theorem of Chevalley-Warning (see [130, Theorem 9.24]). A proof using group algebras may be found in [71, Proposition 5.8.1], and for a generalization see [126]. \( \square \)

**Theorem 6.13.** Let \( G = C_{n_1} \oplus C_{n_2} \) with \( 1 \leq n_1 | n_2 \). Then
\[ s(G) = 2n_1 + 2n_2 - 3, \quad \eta(G) = 2n_1 + n_2 - 2 \quad \text{and} \quad d(G) = n_1 + n_2 - 2 = d^*(G). \]

Proof. By Corollaries 6.11 and 4.4, the result holds for \( n_1 = 1 \). Suppose that \( n_1 > 1 \) and note that \( \exp(G) = n_2 \). By Lemma 4.3 we have \( d^*(G) \leq d(G) \). Now Lemma 6.5 implies that
\[ \eta(G) \geq 2n_1 + n_2 - 2 \quad \text{and} \quad s(G) \geq \eta(G) + n_2 - 1 \geq 2n_1 + 2n_2 - 3. \]
Thus it remains to show that \( s(G) \leq 2n_1 + 2n_2 - 3 \) and \( d(G) \leq n_1 + n_2 - 2 \).

We use induction on \( \exp(G) \). If \( p \in \mathbb{P} \) and \( G = C_p \oplus C_p \), then \( d(G) = 2p - 2 \) by Theorem 4.10, and Proposition 6.12 implies \( s(G) \leq 4p - 3 \).

Assume now that \( p \in \mathbb{P} \), \( p | n_1 \), \( p < n_2 \) and set \( n_i = p^{-1}n_i \) for \( i \in \{1, 2\} \). Then the assertions are true for the groups \( pG \cong C_{n_1} \oplus C_{n_2} \) and \( G/pG \cong C_p \oplus C_p \). By Lemma 6.8.1 we obtain
\[ s(G) \leq (s(pG) - 1)p + s(G/pG) \leq (2m_1 + 2m_2 - 4)p + (4p - 3) = 2n_1 + 2n_2 - 3, \]
and Lemma 6.8.3 implies
\[ d(G) \leq d(pG)p + \max \{d(G/pG), \eta(G/pG) - p - 1\} \]
\[ = (m_1 + m_2 - 2)p + \max \{2p - 2, (3p - 2) - p - 1\} = n_1 + n_2 - 2. \]

The next corollary was first proved in [51, Theorem 6.7].

**Corollary 6.14.** Let \( \exp(G) = n \). If \( G \) is either a \( p \)-group or \( r(G) \leq 2 \), then \( s_{n(G)}(G) = d(G) + n \).

Proof. If \( G \) is a \( p \)-group, then the assertion follows from Theorem 4.10 and from Lemma 6.6.3.

Suppose that \( G = C_{n_1} \oplus C_{n_2} \) with \( 1 \leq n_1 | n_2 \). Then Lemma 6.6.3 implies that \( d(G) + n_2 \leq s_{n(G)}(G) \) whence it remains to prove that \( s_{n(G)}(G) \leq d(G) + n_2 = n_1 + 2n_2 - 2 \). If \( n_1 = 1 \), this follows from Theorem 6.13 and again from Lemma 6.6.3. Suppose that \( n_1 > 1 \), and let \( S \in \mathcal{F}(G) \) be a sequence of length \( |S| = n_1 + 2n_2 - 2 \). We have to show that \( S \) has a zero-sum subsequence of length \( n_2 \) or \( 2n_2 \).

Let \( K = G \oplus C_{n_2} = G \oplus \langle e \rangle \) with \( \langle e \rangle = n_2 \), so that every \( h \in G \oplus C_{n_2} \) has a unique representation \( h = g + je \), where \( g \in G \) and \( j \in [0, n_2 - 1] \). We define \( \psi : G \to K \) by \( \psi(g) = g + e \) for every \( g \in G \). Thus it suffices to show that \( \psi(S) \) has a nontrivial zero-sum subsequence. We distinguish two cases.

**CASE 1:** \( n_1 = n_2 \).

We set \( n = n_1 \) and proceed by induction on \( n \). If \( n \) is prime, then \( G \) is a \( p \)-group and the assertion holds. Suppose that \( n \) is composite, \( p \) a prime divisor of \( n \) and \( \varphi : K \to K \) the multiplication by \( p \). Then \( pG \cong C_{n/p} \oplus C_{n/p} \) and \( \text{Ker}(\varphi) \cong C_p \). Since by Theorem 6.13, \( s(pG) = 4(n/p) - 3 \) and \( |S| = 3n - 2 \geq (3p - 4)(n/p) + 4n/p - 3 \), \( S \) admits a product decomposition \( S = S_1 \cdot \ldots \cdot S_{3p-3}S' \) such that, for all \( i \in [1, 3p - 3] \), \( \varphi(S_i) \) has sum zero and length \( |S_i| = n/p \) (see Lemma 6.7.1). Then
Let \( m = n_1^{-1} n_2 \) and let \( \varphi : K = C_{n_1} \oplus C_{n_2} \to C_{n_1} \oplus m C_{n_2} \) be a map which is the identity on the first component and the multiplication by \( m \) on the second and on the third component whence \( \text{Ker}(\varphi) = C_m \oplus C_m \) and \( \varphi(G) = C_{n_1} \oplus C_{n_1} \). Since \( s(C_{n_1} \oplus C_{n_1}) = 4n_1 - 3 \) and \( |S| = n_1 + 2n_2 - 2 \geq (2m - 3)|n_1 + (4n_1 - 3)\), \( S \) admits a product decomposition \( S = S_1 \cdots S_{2m-2} S' \), where for all \( i \in \{ 1, 2m - 2 \} \), \( \varphi(S_i) \) has sum zero and length \( |S_i| = n_1 \). Then \( |S'| = 3n_1 - 2 \), and since by CASE 1, \( s, n_1 \in [C_{n_1} \oplus C_{n_1}] = 3n_1 - 2 \), the sequence \( S' \) has a subsequence \( S_{2m-1} \) such that \( \varphi(S_{2m-1}) \) has sum zero and length \( |S_{2m-1}| \in \{ n_1, 2n_1 \} \).

This implies that

\[
\prod_{i=1}^{2m-2} \sigma(\psi(S_i)) \in \mathcal{F}(\text{Ker}(\varphi)).
\]

Since \( D(\text{Ker}(\varphi)) = 3p - 2 \), there exists a nonempty subset \( I \subset \{ 1, 2m - 2 \} \) such that

\[
\sum_{i \in I} \sigma(\psi(S_i)) = 0 \quad \text{whence} \quad \prod_{i \in I} \psi(S_i)
\]

is a nontrivial zero-sum subsequence of \( \psi(S) \).

**CASE 2:** \( n_2 > n_1 \).

Let \( m = n_1^{-1} n_2 \) and let \( \varphi : K = C_{n_1} \oplus C_{n_2} \to C_{n_1} \oplus m C_{n_2} \) be a map which is the identity on the first component and the multiplication by \( m \) on the second and on the third component whence \( \text{Ker}(\varphi) = C_m \oplus C_m \) and \( \varphi(G) = C_{n_1} \oplus C_{n_1} \). Since \( s(C_{n_1} \oplus C_{n_1}) = 4n_1 - 3 \) and \( |S| = n_1 + 2n_2 - 2 \geq (2m - 3)|n_1 + (4n_1 - 3)\), \( S \) admits a product decomposition \( S = S_1 \cdots S_{2m-2} S' \), where for all \( i \in \{ 1, 2m - 2 \} \), \( \varphi(S_i) \) has sum zero and length \( |S_i| = n_1 \). Then \( |S'| = 3n_1 - 2 \), and since by CASE 1, \( s, n_1 \in [C_{n_1} \oplus C_{n_1}] = 3n_1 - 2 \), the sequence \( S' \) has a subsequence \( S_{2m-1} \) such that \( \varphi(S_{2m-1}) \) has sum zero and length \( |S_{2m-1}| \in \{ n_1, 2n_1 \} \).

This implies that

\[
\prod_{i=1}^{2m-1} \sigma(\psi(S_i)) \in \mathcal{F}(\text{Ker}(\varphi)).
\]

Since \( D(\text{Ker}(\varphi)) = 2m - 1 \), there exists a nonempty subset \( I \subset \{ 1, 2m - 1 \} \) such that

\[
\sum_{i \in I} \sigma(\psi(S_i)) = 0 \quad \text{whence} \quad \prod_{i \in I} \psi(S_i)
\]

is a nontrivial zero-sum subsequence of \( \psi(S) \).

We briefly discuss the state of the art concerning groups of higher rank (more detailed information can be found in [51]). A conjecture by W. Gao states that we always have \( \eta(G) = s(G) - \exp(G) + 1 \). This was recently proved for \( p \)-groups \( G \), where \( p \) is odd and \( D(G) = 2 \exp(G) - 1 \) ([123]). C. Elsholtz et al. showed that, for all odd \( n \geq 3 \),

\[
\eta(C_n) \geq 8n - 7, \quad s(C_n) \geq 9n - 8, \quad \eta(C_n^2) \geq 19n - 18 \quad \text{and} \quad s(C_n^2) \geq 20n - 19,
\]

and it is conjectured that all bounds are sharp (see [29, 28, 27, 113] for recent results).

It is conjectured that, if \( r(G) = 3 \) or \( G = C_n \) with \( n, r \geq 3 \), then \( d(G) = d^*(G) \). On the other hand, for every \( r \geq 4 \) there are infinitely many groups \( G \) of rank \( r(G) = r \) such that \( d(G) > d^*(G) \) (see [75] and [48, Theorem 3.3]). We end with a result (see [13]) providing more groups \( G \) with \( d(G) = d^*(G) \) and whose proof demonstrates once more the power of the inductive method (for recent results see [6, 4]).

**Theorem 6.15.** Let \( G = K \oplus C_{km} \) where \( k, m \in \mathbb{N} \) and \( K \subset G \) is a subgroup with \( \exp(K) | m \). If \( d(K \oplus C_m) = d(K) + m - 1 \) and \( \eta(K \oplus C_m) \leq d(K) + 2m \), then \( d(G) = d(K) + km - 1 \).

**Proof.** Clearly, we have \( d(G) \geq d(K) \). If \( d(C_{km}) = d(K) + km - 1 \), then \( d(G) = d(K) + km - 1 \).

We consider the map \( \varphi : G \to G \) which maps an element \( g = h + a \), with \( h \in K \) and \( a \in C_{km} \), to \( h + ka \) for all \( g \in G \). Then \( \text{Ker}(\varphi) = C_k \) and \( \varphi(G) = K \oplus C_m \). Since

\[
|\varphi(S)| = |S| = (k - 2) m + d(K) + 2m \quad \text{and} \quad \eta(K \oplus C_m) \leq d(K) + 2m,
\]

Lemma 6.7 provides us with a product decomposition

\[
S = S_1 \cdots S_{k-1} S'
\]
where $S_1, \ldots, S_{k-1}, S' \in \mathcal{F}(G)$ and, for every $i \in [1, k]$, $\varphi(S_i)$ has sum zero and length $|S_i| \in [1, \exp(K \oplus C_m)] = [1, m]$. Thus we get
\[ |S'| = |S| - \sum_{i=1}^{k-1} |S_i| \geq |S| - (k - 1)m = d(K) + m = D(K \oplus C_m), \]
and hence $S'$ has a subsequence $S_k$ such that $\varphi(S_k)$ has sum zero. Thus
\[ \prod_{i \in I} \sigma(S_i) \in \mathcal{F}(\ker(\varphi)), \]
and there is a nonempty subset $I \subset [1, k]$ such that $\prod_{i \in I} \sigma(S_i)$ has sum zero. Hence $\prod_{i \in I} S_i$ is a nontrivial zero-sum subsequence of $S$. \hfill \Box

**Corollary 6.16.** Let $G = K \oplus C_{km}$ where $k, m \in \mathbb{N}$, $p \in \mathbb{P}$ a prime, $m$ a power of $p$ and $K \subset G$ is a $p$-subgroup with $d(K) \leq m - 1$. Then $d(G) = d^*(G)$.

**Proof.** Since $K \oplus C_m$ is a $p$-group, Theorem 4.10 implies that
\[ d(K \oplus C_m) = d^*(K \oplus C_m) = d^*(K) + m - 1 = d(K) + m - 1. \]
Since $\exp(K)$ is a $p$-power and $\exp(K) - 1 \leq d(K) \leq m - 1$, it follows that $\exp(K)$ divides $m$. By Lemma 6.6 we infer that
\[ \eta(K \oplus C_m) \leq d(K \oplus C^2_m) + 1 = d(K) + 2m - 1. \]
Thus all assumptions of Theorem 6.15 are satisfied and we obtain that
\[ d(G) = d(K) + km - 1 = d^*(K) + km - 1 = d^*(G). \] \hfill \Box

### 7. Inverse zero-sum problems and arithmetical consequences

The investigation of inverse problems has a long tradition in combinatorial number theory (see [107, 37]), and more recently it has been promoted by applications in the theory of non-unique factorizations. In this section we discuss the inverse problems associated to the invariants $D(G)$, $\eta(G)$ and $\sigma(G)$. More precisely, we investigate the structure of sequences of length $D(G) - 1$ (or $\eta(G)$, respectively) that do not have a zero-sum subsequence (of the required length). Recent results on the structure of $\Sigma(S)$ for (long) zero-sum free sequences may be found in [9, 58, 127, 133, 60].

We start with cyclic groups, then we deal with groups of the form $G = C_n^r$, and finally we outline some consequences in factorization theory.

**7.A Cyclic groups**

Clearly, we can rephrase Corollary 4.4.1 as follows: let $G$ be cyclic of order $n \geq 2$ and $S \in \mathcal{F}(G)$ a sequence of length $D(G) - 1 = \eta(G) - 1$. Then $S$ has no (short) zero-sum subsequence if and only if $S = g^{n-1}$ for some $g \in G$ with $\text{ord}(g) = n$.

We present a strong structural result on long zero-sum free sequences recently achieved by S. Savchev and Fang Chen ([116]). Among others their result settles a problem on the index of zero-sum sequences (studied in [16, 46, 112, 18], see Corollary 7.9) and provides information on multiplicities of elements, a topic studied by many authors before (Corollary 7.10).

**Definition 7.1.**
1. Let \( g \in G \) be a non-zero element with \( \text{ord}(g) = n < \infty \). For a sequence
\[ S = (n_1g) \cdot \ldots \cdot (n_lg), \quad \text{where } l \in \mathbb{N}_0 \text{ and } n_1, \ldots, n_l \in [1, n], \]
we define
\[ \|S\|_g = \frac{n_1 + \ldots + n_l}{n}. \]
Obviously, \( S \) has sum zero if and only if \( \|S\|_g \in \mathbb{N}_0 \).

2. Let \( S \in F(G) \) be a sequence for which \( \langle \text{supp}(S) \rangle \subset G \) is cyclic. Then we call
\[ \text{ind}(S) = \min \{\|S\|_g \mid g \in G \text{ with } \langle \text{supp}(S) \rangle = \langle g \rangle \} \]
the index of \( S \).

3. If \( G \) is cyclic, then let \( \|G\| \) denote the smallest integer \( l \in \mathbb{N} \) such that every minimal zero-sum sequence \( S \in F(G) \) of length \( |S| \geq l \) satisfies \( \text{ind}(S) = 1 \).

**Lemma 7.2.** Let \( G \) be cyclic and \( S \in F(G) \). Then
\[ \text{ind}(S) = \min \{\|S\|_g \mid g \in G \text{ with } \langle \text{supp}(S) \rangle \subset \langle g \rangle \}, \]
\[ = \min \{\|S\|_g \mid g \in G \text{ with } G = \langle g \rangle \}. \]

**Proof.** We set \( |G| = n \).
\[ I_1 = \min \{\|S\|_g \mid g \in G \text{ with } \langle \text{supp}(S) \rangle \subset \langle g \rangle \} \quad \text{and} \quad I_2 = \min \{\|S\|_g \mid g \in G \text{ with } G = \langle g \rangle \}. \]
Let \( |S| = l, g \in G \) with \( \text{ord}(g) = m \) and \( S = (a_1g) \cdot \ldots \cdot (a_lg) \) with \( a_1, \ldots, a_l \in [1, m] \) such that \( \|S\|_g = I_1 \).
First we verify that \( I_1 = I_2 \) and then we show that \( I_1 = \text{ind}(S) \).

1. Obviously, we have \( I_1 \leq I_2 \), and it remains to verify the reverse inequality. There is an element \( h \in G \) with \( \langle h \rangle = G \) and \( \frac{n}{m}h = g \). Thus we obtain
\[ S = (a_1 \frac{n}{m} - h) \cdot \ldots \cdot (a_l \frac{n}{m} - h) \quad \text{with} \quad a_1 \frac{n}{m}, \ldots, a_l \frac{n}{m} \in [1, n], \]
\[ \|S\|_h = \frac{n}{m}a_1 + \ldots + \frac{n}{m}a_l = a_1 + \ldots + a_l = \|S\|_g \]
and hence \( I_2 \leq \|S\|_h = \|S\|_g = I_1 \).

2. Obviously, we have \( I_1 \leq \text{ind}(S) \), and it remains to verify the reverse inequality. We set \( \langle a_1g, \ldots, a_lg \rangle = K \) and pick an \( a \in [1, m] \) with \( a \leq m \) and \( K = \langle ag \rangle \). Then \( \text{ord}(ag) = a^{-1}m \). For every \( i \in [1, l] \) we have
\[ a_i \in \langle ag \rangle = \langle ag, 2ag, \ldots, (a^{-1}m)ag \rangle \quad \text{and hence} \quad a_i = a_i' \quad \text{with} \quad a_i' \in [1, a^{-1}m]. \]
Thus we obtain
\[ S = (a_1'ag) \cdot \ldots \cdot (a_l'ag), \]
\[ \|S\|_g = \frac{a_1' + \ldots + a_l'}{m} = \frac{a_1' + \ldots + a_l'}{a^{-1}m} = \|S\|_g \]
and hence \( I_1 = \|S\|_h = \|S\|_g \geq \text{ind}(S) \). \( \square \)

**Definition 7.3.** A sequence \( S \in F(G) \) is called
- smooth if \( S = (n_1g) \cdot \ldots \cdot (n_lg) \), where \( l = |S| \in \mathbb{N}, g \in G, 1 = n_1 \leq \ldots \leq n_l, n = n_1 + \ldots + n_l < \text{ord}(g) \) and \( \Sigma(S) = \{g, 2g, \ldots, ng\} \) (in this case we say more precisely that \( S \) is \( g \)-smooth).
- a splittable atom if \( S = (g_1 + g_2)T \) for some \( g_1, g_2 \in G \) and \( T \in F(G) \) such that \( S \in \mathcal{A}(G) \) and \( g_1g_2T \in \mathcal{A}(G) \).

**Lemma 7.4.** Let \( g \in G \) and \( k, n_1, \ldots, n_l \in \mathbb{N} \) such that \( l \geq k/2 \) and \( n = n_1 + \ldots + n_l < k \leq \text{ord}(g) \).
If \( 1 \leq n_1 \leq \ldots \leq n_l \) and \( S = (n_1g) \cdot \ldots \cdot (n_lg) \), then \( \Sigma(S) = \{g, 2g, \ldots, ng\} \) and \( S \) is \( g \)-smooth.

**Proof.** We start with the following assertion.
A. For every $i \in [0, l - 1]$ we have $n_{i+1} \leq 1 + n_1 + \ldots + n_i$, and in particular we have $n_1 = 1$.

Proof of A. Assume to the contrary that there is an $i \in [0, l - 1]$ such that $n_{i+1} \geq 2 + n_1 + \ldots + n_i$. Then for all $j \in [i+1, l]$ we have $n_j \geq n_{i+1} \geq 2 + i$ and therefore

$$k > n_1 + \ldots + n_l \geq i + (l-i)(2+i) = 2l + i(l-i-1) \geq k,$$

a contradiction.

For every $i \in [1, l]$ we set $S_i = (n_{1g}) \ldots (n_{ig})$ and assert that $\Sigma(S_i) = \{jg \mid j \in [1, n_1 + \ldots + n_i]\}$. We proceed by induction on $i$. For $i = 1$, this hold since $n_1 = 1$. If $i \in [1, l-1]$, then A and the induction hypothesis imply that

$$\Sigma(S_{i+1}) = \Sigma(S_i) \cup \left(n_{i+1}g + (\Sigma(S_i) \cup \{0\})\right)$$

$$= \{jg \mid j \in [1, n_1 + \ldots + n_i] \cup \{jg \mid j \in [n_{i+1}, n_1 + \ldots + n_i + n_{i+1}]\}$$

$$= \{jg \mid j \in [1, n_1 + \ldots + n_{i+1}]\}.$$ 

\[\square\]

Lemma 7.5. Let $S \in \mathcal{F}(G)$ and $b \in G$ such that $Sb \in \mathcal{A}^*(G)$ and $|\Sigma(Sb)| = |\Sigma(S)| + 1$.

1. We have $|\Sigma(S)| = \{b, 2b, \ldots, sb\} \cup P_1 \cup \ldots \cup P_m$, where $s \in [1, \text{ord}(b) - 2]$, $m \in \mathbb{N}_0$ and $P_1, \ldots, P_m \in G/\langle b \rangle$ are distinct cosets different from $\langle b \rangle$. Moreover, $sb = \sigma(S)$ and $|\Sigma(Sb^j)| = |\Sigma(Sb^{j-1})| + 1$ for all $j \in [1, \text{ord}(b) - s]$.

2. If $c \in G$ is such that $Sc \in \mathcal{A}^*(G)$ and $|\Sigma(Sc)| = |\Sigma(S)| + 1$, then $c = b$.

Proof. 1. Since $Sb \in \mathcal{A}^*(G)$, $|\Sigma(Sb)| = |\Sigma(S)| + 1$ and $\sigma(S) + b \in \Sigma(Sb)$, it follows that $\Sigma(Sb) \setminus \Sigma(S) = \{\sigma(S) + b\}$, and since $b \in \Sigma(Sb)$ and $\sigma(S) \neq 0$, we obtain that $b \in \Sigma(S)$. Let $s \in \mathbb{N}$ be maximal such that $\{b, 2b, \ldots, sb\} \subset \Sigma(S)$. Then $(s+1)b \in \Sigma(Sb)$, hence $(s+1)b = \sigma(S) + b$ and $sb = \sigma(S)$. Moreover, $Sb \in \mathcal{A}^*(G)$ implies that $s+1 < \text{ord}(b)$.

In order to prove that $\Sigma(S) \setminus \{b, 2b, \ldots, sb\}$ is the union of proper cosets of $\langle b \rangle$ in $G$, we have to verify that $c \in \Sigma(S) \setminus \{b, 2b, \ldots, sb\}$ implies that $c + b \in \Sigma(S) \setminus \{b, 2b, \ldots, sb\}$. Indeed, if $c \in \Sigma(S) \setminus \{b, 2b, \ldots, sb\}$, then $c + b \in \Sigma(Sb)$. If $c + b \notin \Sigma(S) \setminus \{b, 2b, \ldots, sb\}$, then $c + b = tb$ for some $t \in [1, s+1]$, and thus $c = (t-1)b \in \{0, b, 2b, \ldots, sb\}$, a contradiction. Hence it follows that $c + b \notin \Sigma(S) \setminus \{b, 2b, \ldots, sb\}$.

If $j \in [1, \text{ord}(b) - s]$, then

$$\Sigma(Sb^j) = \{b, 2b, \ldots, (s+j)b\} \cup P_1 \cup \ldots \cup P_m = \Sigma(Sb^{j-1}) \cup \{(s+j)b\},$$

and since $s+j \leq \text{ord}(b)$, we obtain $|\Sigma(Sb^j)| = |\Sigma(Sb^{j-1})| + 1$.

2. Let $c \in G$ be such that $Sc \in \mathcal{A}^*(G)$ and $|\Sigma(Sc)| = |\Sigma(S)| + 1$. Then $R = \{c, b+c, 2b+c, \ldots, sb+c\} \subset \Sigma(Sc)$, and since $|R| \geq 2$ we have $R \cap \Sigma(S) \neq \emptyset$. Suppose there is some $j \in [1, m]$ such that $R \cap P_j \neq \emptyset$. Then $R \subset P_j$, but $sb+c = \sigma(S) + c \in \Sigma(Sc) \setminus \Sigma(S)$ and thus $sb+c \notin P_j$, a contradiction. Hence it follows that $R \setminus \{b, 2b, \ldots, sb\} \neq \emptyset$, say $rb+c = tb$ for some $r \in [0, s]$ and $t \in [1, s]$. Thus we obtain $c = (t-r)b$ and $R = \{(t-r)b \mid j \in [0, s]\}$, if $t \leq r$, this implies $0 \in R$, a contradiction. If $t > r+2$, we obtain $\{(s+1)b, (s+2)b\} \subset R \setminus \Sigma(S) \subset \Sigma(Sc) \setminus \Sigma(S)$, contradicting $|\Sigma(Sc)| = |\Sigma(S)| + 1$. Therefore we get $t = r+2$ and $c = b$.

\[\square\]

Lemma 7.6. Let $G$ be cyclic of order $n \geq 3$, $S = S_1S_2 \in \mathcal{A}^*(G)$ where $|S| = l \geq \frac{n+1}{2}$, $2 \leq |S_1| = k + 1 \leq l$ and $|\Sigma(S_1)| \geq 2k + 1$. Then there is a decomposition $S_2 = S_2c$ with $S_2 \in \mathcal{F}(G)$ and $c \in G$ such that $|\Sigma(S)| = |\Sigma(S_2)| + 1$.

Proof. Let $t \in \mathbb{N}_0$ be maximal such that there is a decomposition $S_2 = g_1 \cdot \ldots \cdot g_T$, where $g_1, \ldots, g_T \in G$ and $T \in \mathcal{F}(G)$ are such that

$$|\Sigma(S_1g_1 \cdot \ldots \cdot g_{j-1})| \geq |\Sigma(S_1g_1 \cdot \ldots \cdot g_{j-1})| + 2 \quad \text{for all} \quad j \in [1, l].$$

Then we have
\[ n - 1 \geq |\Sigma(S)| \geq |\Sigma(S_1g_1 \cdots g_k)| \geq |\Sigma(S_1)| + 2t \geq 2k + 1 + 2t. \]
Therefore it follows that \(2t + 2 \leq n - 2k\), whence \(t + 1 \leq n/2 - k < t - k\) and \(|T| = |S| - |S_1| - t = l - (k + 1) - t > 0\). Let \(c \in \text{supp}(T)\). Since \(|\Sigma(S_1g_1 \cdots g_k)| = |\Sigma(S_1g_1 \cdots g_{k-1})| + 1\) (by the maximality of \(t\)), Lemma 7.5 implies that
\[
\Sigma(S_1g_1 \cdots g_k) = \{c, 2c, \ldots, sc\} \cup P_1 \cup \ldots \cup P_m,
\]
where \(s \in [1, \text{ord}(c) - 2], m \in \mathbb{N}_0\) and \(P_1, \ldots, P_m \in G/\langle c \rangle\) are proper cosets. If \(d \in \text{supp}(c^{-1}T)\), then (again by the maximality of \(t\)) \(|\Sigma(S_1g_1 \cdots g_kd)| = |\Sigma(S_1g_1 \cdots g_{k-1})| + 1\), and Lemma 7.5 implies \(d = c\). Hence \(T = c^j\) for some \(j \in [1, \text{ord}(c) - s]\) and \(S'_2 = g_1 \cdots g_{j-1}\) fulfills our requirements. \(\square\)

**Lemma 7.7.** Let \(G\) be cyclic of order \(n \geq 3\), \(S \in A^*(G)\) with \(|\Sigma(S)| = G^*, |S| = t \geq n^{1/2}, a \in \text{supp}(S)\) and \(S_a\) a maximal \(a\)-smooth subsequence of \(S\). If \(S_a \neq S\), then \((-\sigma(S)) \parallel |S_a|^{-1} S\).

**Proof.** Let \(S_a = (s_1a) \cdots (s_k a)\), where \(k, s_1, \ldots, s_k \in \mathbb{N}, 1 = s_1 \leq s_2 \leq \ldots \leq s_k, s = s_1 + \ldots + s_k < \text{ord}(a)\), and assume that \(S_a \neq S\). Then \(S = S_b S_a\), where \(b \in G\) and \(S_a \in F(G)\), and we have \(|\Sigma(S_a)| = |P_1| \cup |P_2|\) where \(P_1 = \Sigma(S_a) = \{a, 2a, \ldots, sa\}\) and \(P_2 = b + (\{\Sigma(S_a) \cup \{0\}\}) = \{b, b + a, \ldots, b + sa\}\). We shall prove that

**A.** \(P_1 \cap P_2 = \emptyset\).

**Proof of A.** The assertion is obvious if \(b \notin \{a\}\). Thus assume that \(b = ta \) for some \(t \in [1, \text{ord}(a) - 1]\). Then \(|\Sigma(S_a)\) = \(|\Sigma(S)| = G^*\) and \(|S_a| = \Sigma(s_1 + \ldots + s_k)\), with \(s = a + \ldots + a\). If \(t \leq s\), then \(t + s \geq s + 1 + \text{ord}(a)\), a contradiction. Hence \(s < t < \text{ord}(a)\) and \(P_1 \cap P_2 = \emptyset\).

We apply Lemma 7.6 with \(S_1 = S_a\). Note that \(2 \leq k + 1 = |S_a| \leq |S| = t + 1\) and
\[ n - 1 \geq |\Sigma(S_a)| = |P_1| + |P_2| = 2s + 1 \geq 2k + 1. \]
Thus we arrive at a decomposition \(S_a = S'_a c\) for some \(S'_a \in F(G)\) and \(c \in G\) such that \(|\Sigma(S)| = |\Sigma(S_1 S'_a)| + 1 = |G| - 1\). Since \(|\Sigma(S)| = \Sigma(S_1 S'_a) \cup \{\sigma(S)\}\) and \(-c \notin \Sigma(S_1 S'_a),\) it follows that \(c = \sigma(S)\), whence \(-\sigma(S) \parallel |S_a|^{-1} S\). \(\square\)

**Theorem 7.8 (Saxeclev-Chen).** Let \(G\) be cyclic of order \(n \geq 3\).

1. If \(S \in A^*(G)\) and \(|S| \geq n^{1/2}\), then \(S\) is \(g\)-smooth for some \(g \in G\) with \(\text{ord}(g) = n\).
2. Let \(U \in A(G)\) be of length \(|U| \geq \lfloor n^2/2 \rfloor + 2\). Then \(\text{ind}(U) = 1\) and if \(U\) is not splittable, then \(U \equiv g^n\) for some \(g \in G\).

**Proof.** We may suppose that \(U = g_0 S\) with \(|S| = l \geq n^{1/2}\). First we show that \(S\) is \(g\)-smooth for some \(g \in G\). Then we show \(\text{ind}(U) = 1\) and \(\text{ord}(g) = n\).

1. Pick a sequence \(S' \in A^*(G)\) such that \(|S| = |S'| |S'|\) is maximal. Then \(|\Sigma(S')| = G^*\) and \(m = |S'| \geq |S| \geq n^{1/2}\). Let \(a \in \text{supp}(S')\) and \(S_b\) be a maximal \(a\)-smooth subsequence of \(S'\). If \(S_b \neq S'\) and \(h = -\sigma(S_b)\), then \(h|S_b^{-1} S'\) by Lemma 7.7. Now let \(S_b\) be a maximal \(h\)-smooth subsequence of \(S'\). Then \(h \parallel S_b^{-1} S'\), since otherwise \(hS_b\) would be a longer \(h\)-smooth subsequence of \(S'\). Hence again Lemma 7.7 implies that \(S_b = S'\).

In any case \(S'\) is smooth, and thus we may assume that \(S' = (n_1 g) \cdots (n_m g)\) and \(S = (n_1 g) \cdots (n_m g)\), where \(g \in G, m \in \mathbb{N}, n_1, \ldots, n_m \in \mathbb{N}, l \leq m \leq n_1 + \ldots + n_m < \text{ord}(g) \leq n < 2l\) and \(1 \leq n_1 \leq \ldots \leq n_m\). Thus Lemma 7.4 (with \(k = \text{ord}(g))\) implies that \(S\) is \(g\)-smooth.

2. By 1., \(S = (n_1 g) \cdots (n_m g)\) is \(g\)-smooth, whence \(n_1, \ldots, n_m \in \mathbb{N}\) and \(s = n_1 + \ldots + n_m < \text{ord}(g)\). Then \(g_0 = \sigma(S) = sg\) and \(U = (n_0 g)(n_1 g) \cdots (n_m g)\) with \(n_0 = \text{ord}(g) - s \in \mathbb{N}\) and hence \(n_0 + \ldots + n_m = \text{ord}(g)\).

Let \(m \in \mathbb{N}\) with \(\text{ord}(g) = n/m\) and \(g' \in G\) with \(mg' = g\). Then \(U = (mn_0 g') \cdots (mn_m g')\) and...
Corollary 7.9 was achieved independently by S. Savchev and F. Chen, and by P. Yuan (see [132, Theorem 3.1] and [116, Proposition 10]).

Corollary 7.9. Let \( G \) be cyclic of order \( n \geq 1 \). If \( n \in \{1, 2, 3, 4, 5, 7\} \), then \( l(G) = 1 \), and otherwise we have \( l(G) = \left[ \frac{n}{2} \right] + 2 \).

Proof. If \( n \leq 4 \), it can be seen immediately that \( l(G) = 1 \). If \( n \in \{5, 7\} \), a longer (but straightforward) case distinction shows that again \( l(G) = 1 \) holds. Suppose that \( n \in \mathbb{N}_{\geq 6 \setminus \{7\}} \), and let \( g \in G \) with \( \text{ord}(g) = n \). Since the sequence

\[
S = \begin{cases} 
  g^{\frac{n+2}{2}} (n^2 g) & \text{if } n \text{ is even}, \\
  g^{\frac{n+2}{2}} (\frac{n-2}{2} g)^2 (\frac{n+1}{2} g) & \text{if } n \text{ is odd},
\end{cases}
\]

is a minimal zero-sum sequence with \( \text{ind}(S) = 2 \), it follows that \( l(G) \geq \left[ \frac{n}{2} \right] + 2 \), and hence equality holds by Theorem 7.8.2. \( \square \)

The second statement of Corollary 7.10 was first proved by J.D. Bovey, P. Erdős and I. Niven ([10] and the fourth statement by A. Geroldinger and Y. ıdil Hamidoune ([112]). Note that the bounds given in 7.10.4 are attained ([71, Example 5.4.7]).

Corollary 7.10. Let \( G \) be cyclic of order \( n \geq 3 \), \( S \in \mathcal{F}(G) \) a zero-sum free sequence of length

\[
|S| \geq \frac{n+1}{2}.
\]

1. For all \( g \in \text{supp}(S) \) we have \( \text{ord}(g) \geq 3 \).
2. There exists some \( g \in \text{supp}(S) \) with \( \nu_g(S) \geq 2|S| - n + 1 \).
3. There exists some \( g \in \text{supp}(S) \) with \( \nu_g(S) \geq |S| - \frac{n-1}{2} \).
4. There exists some \( g \in \text{supp}(S) \) with \( \text{ord}(g) = n \) such that

\[
\nu_g(S) \geq \frac{n+5}{6} \quad \text{if } n \text{ is odd, and } \quad \nu_g(S) \geq 3 \quad \text{if } n \text{ is even}.
\]

Proof. 1. The assertion is clear for odd \( n \). Thus suppose that \( n = 2m \) for some \( m \geq 2 \). By Theorem 7.8, \( S = (n_1 g) \cdots (n_2 g) \) for some \( g \in G \) with \( \text{ord}(g) = n \), \( 1 = n_1 \leq \ldots \leq n_2 \) and \( \Sigma(S) = \{ g, 2g, \ldots , sg \} \) where \( s = n_1 + \ldots + n_2 \). Assume to the contrary that \( S \) contains some element of order 2. Then there is an \( i \in [1, l] \) with \( n_i = m \) and hence \( s = n_1 + \ldots + n_2 \geq l - 1 + m \geq 2m \), a contradiction to \( S \)-zero-sum free.

2. We write \( S \) in the form \( S = S_1 \cdots S_k (gh)^l g^{m-l} \), where \( k, m \in \mathbb{N}_0, l \in [0, m], g \neq h, S_1, \ldots , S_k \) are squarefree, and \( |S_i| = 3 \) for all \( i \in [1, k] \). Clearly, we have \( |\Sigma(gh)| = 3 \), and using 1. we obtain that \( |\Sigma(S_i)| \geq 6 \) for all \( i \in [1, k] \). By Corollary 6.3 it follows that

\[
n - 1 \geq |\Sigma(S)| \geq 6k + 3l + (m - l) \geq 6k + 2l + 2m - \nu_g(S) = 2|S| - \nu_g(S)
\]

and therefore \( \nu_g(S) \geq 2|S| - n + 1 \).

3. and 4. The sequence \( S_1 = (\sigma(S))S \) is a minimal zero-sum sequence of length \( |S_1| \geq (n+3)/2 \). Thus Corollary 7.9 implies that \( \text{ind}(S_1) = 1 \). Thus there is an element \( h \in G \) with \( \text{ord}(h) = n \) such that

\[
S_1 = (xh) h^x (2h)^x (x_1 h) \cdots (x_i h),
\]
where $x \in [1, n-1]$, $xh = -\sigma(S)$, $u, v, t \in \mathbb{N}_0$, $x_1, \ldots, x_t \in [3, n-1]$ and $x + u + 2v + (x_1 + \ldots + x_t) = n$. Clearly, we have

$$|S| = u + v + t \quad \text{and} \quad u + 2v + 3t = n - r \quad \text{for some} \quad r \in \mathbb{N},$$

which implies that $2u + v = 3|S| - (n - r)$ and hence

$$\max\{u, v\} \geq |S| - \frac{n - r}{3} \geq |S| - \frac{n - 1}{3}.$$

If $n$ is odd, then $\text{ord}(h) = \text{ord}(2h) = n$ and

$$\max\{v_h(S), v_{2h}(S)\} = \max\{u, v\} \geq |S| - \frac{n - 1}{3} \geq \frac{n + 5}{6}.$$

If $n$ is even, then $|S| \geq (n/2) + 1$ and

$$v_h(S) = u = 2|S| - n + r + t \geq 2 + r + t \geq 3. \quad \square$$

Without proof we cite a most recent result by W. Gao et. al. (see [61]).

**Theorem 7.11.** Let $G$ be cyclic of order $n \geq 3$. If $S \in F(G)$ is a zero-sum free sequence of length

$$|S| \geq \frac{6n + 28}{19},$$

then $h(S) \geq \frac{6|S| - n + 1}{17}$.

Next we consider the inverse problem with respect to the $s(G)$-invariant. The first result in this direction was achieved independently by B. Peterson and T. Yuster ([109, Theorem 1]), and by A. Bialostocki and P. Dierker ([7, Lemma 4]). It runs as follows.

**Proposition 7.12.** Let $G$ be cyclic of order $n \geq 2$ and $S \in F(G)$ a sequence of length $|S| = s(G) - 1$. Then the following statements are equivalent:

(a) $S$ has no zero-sum subsequence of length $n$.

(b) $S = (gh)^n - 1$ where $g, h \in G$ with $\text{ord}(g - h) = n$.

Proposition 7.12 was the starting point for a huge variety of investigations (see [11, 34, 12, 43, 62, 8, 131, 63, 95, 65]). We present a recent result, achieved by S. Savchev and F. Chen in [117], which characterizes all sequences of length greater than or equal to $(3n - 1)/2$ that have no zero-sum subsequence of length $n$ (Theorem 7.16). This easily implies Proposition 7.12, and moreover the lower bound is, in a certain sense, best possible (see Remark 7.17). We start with the following result of W. Gao (see [41, Theorem 1]).

**Proposition 7.13** (Gao). Let $S \in F(G)$ be a sequence of length $|S| = |G| + k$ with $k \in \mathbb{N}_0$, and suppose that for every $g \in G$ and every subsequence $T$ of $S$ of length $|T| = k + 1$ the sequence $g + T$ has a zero-sum subsequence. Then

$$\Sigma_{kG}(S) = \bigcap_{g \in G} \Sigma(g + S).$$

In particular, if $h(S) = v_0(S)$, then $\Sigma_{\geq kG}(S) = \Sigma_{kG}(S)$.

Proof. We set $|G| = n$. Let $S = a^hT$ with $h = h(S)$ and $|S| = n + k$. Without restriction we may suppose that $a = 0$. Obviously, we have

$$\Sigma(S) \subseteq \bigcap_{g \in G} \Sigma(g + S) \subseteq \Sigma(S).$$

Hence, for the main statement, it suffices to show that $\Sigma(S) \subseteq \Sigma(S)$. But this inclusion clearly implies the "In particular" statement too. We pick $b \in \Sigma(S)$ and distinguish two cases.

**CASE 1:** $h \geq n$. 

If $b = 0$, then $0^b \mid S$ and $0 = \sigma(0^n) \subset \Sigma_n(S)$. Suppose that $b \neq 0$. Since $b \in \Sigma(S)$, there is a subsequence $T'$ of $T$ with $b = \sigma(T')$. Since $D(G) \leq n$, we may assume that $|T'| \leq n$. This implies that $T'0^{n-|T'|} | S$ and $b = \sigma(T'0^{n-|T'|}) \subset \Sigma_n(S)$.

CASE 2: $h \leq n - 1$.

If $b \neq 0$, then $b \in \Sigma(T)$. If $b = 0$, then $n + k - h \geq k + 1$, and thus the assumption implies that $b \in \Sigma(T)$. Therefore in both cases we have $b \in \Sigma(T)$, and we assert that there is a subsequence $U$ of $T$ with $b = \sigma(U)$ and $|U| \leq [n - h, n]$. If this holds, then $U0^{n-|U|} | S$ and $b = \sigma(U0^{n-|U|}) \subset \Sigma_n(S)$.

Let $U$ be a subsequence of $T$ of maximal length such that $b = \sigma(U)$. By the maximality of $|U|$ it follows that $0 \notin \Sigma(U^{-1}T)$ and hence $|U^{-1}T| \leq k$ by assumption. This implies that $|U| \geq |T| - k = n - h$. If $|U| \leq n$, then we are done. Suppose that $|U| > n$. By Proposition 6.9, $U$ admits a product decomposition $U = U_1 \cdot \ldots \cdot U_p U'$ where all $U_i \in B(G)$ are of length $|U_i| \leq h$ for $i \in [1, p]$ and $U' \in \mathcal{F}(G)$ with $n - h \leq |U'| \leq n$. Since $b = \sigma(U) = \sigma(U')$, the sequence $U'$ has the required property. ☐

Although Proposition 7.12 is a straightforward consequence of the main result 7.16, we give a simple independent proof based on Proposition 7.13.

Proof of Proposition 7.12. \((a) \Rightarrow (b)\) Let $S \in \mathcal{F}(G)$ be a sequence of length $2n - 2$ which has no zero-sum subsequence of length $n$, that is $0 \notin \Sigma_n(S)$. For every $g \in G$ we have $|g + S| = 2n - 2 \geq n$, hence $0 \notin \Sigma(g + S)$ and consequently $\Sigma_n(S) \neq \bigcap_{g \in G} \Sigma(g + S)$. By Proposition 7.13, there is some $g \in G$ and some subsequence $T$ of $S$ such that $|T| = n - 1$ and $g + T$ is zero-sum free. Then Corollary 4.4 implies that $g + T = a^{n-1}$ and thus $T = (a - g)^{n-1}$. Let $c = a - g$ and $S = c^{n-1}U$ for some sequence $U \in \mathcal{F}(G)$. Then $-c + S = 0^{n-1}(-c + U)$. Since $-c + S$ has no zero-sum subsequence of length $n$, it follows that $-c + U$ is zero-sum free whence $-c + U = a^{n-1}$ for some $d \in G$ with $\text{ord}(d) = n$. Thus it follows that $S = c^{n-1}(c + d)^{n-1}$.

\((b) \Rightarrow (a)\) Since $\text{ord}(g - h) = n$, the shifted sequence $-h + S = 0^{n-1}(g - h)^{n-1}$ has no zero-sum subsequence of length $n$, and hence $S$ has no zero-sum subsequence of length $n$. ☐

We continue with a simple observation which will be needed frequently in the sequel. Let $g \in G$ with $\text{ord}(g) = n$ and $S = (n_1 g) \cdot \ldots \cdot (n_l g)$ where $l \in \mathbb{N}_0$ and $n_1, \ldots, n_l \in [1, n]$. Then $n\|S\|_g = n_1 + \ldots + n_l$,

$$g - S = ((n - n_1 + 1)g) \cdot \ldots \cdot ((n - n_l + 1)g).$$

and

$$n\|g - S\|_g = \sum_{i=1}^{l} (n - n_i + 1) = \sum_{i=1}^{l} (n - n_i) + |S|.$$  

Proposition 7.14. Let $G$ be cyclic of order $n \geq 3$, $k \in [1, n - 1]$, $g \in G$ with $\text{ord}(g) = n$ and $S, S_1, S_2 \in \mathcal{F}(G)$ such that $S = S_1S_2$, $|S| = n + k - 1$, $\|S\|_g < 1$ and $\|g - S\|_g < 1$.

1. $S$ has no zero-sum subsequence of length $n$.

2. $k \leq |S_1| < n, k \leq |S_2| < n$ and $h - a \geq k$ where $a, b \in [1, n]$, $(ag) \mid S_1$ and $(bg) \mid S_2$. In particular, $\gcd(S_1, S_2) = 1$.

3. \(i\) We have

$$v_g(S) + v_0(S) \geq 2k, \max\{v_g(S), v_0(S)\} \geq k \text{ and } \min\{v_g(S), v_0(S)\} \geq 2k - n + 1.$$  

\(ii\) The following statements are equivalent:

(a) $v_g(S) + v_0(S) = 2k$.

(b) $S_1 = g^{2p-n+1}(2g)^{n-1-p}$ and $S_2 = g^{2q-n+1}(-g)^{n-1-q}$ where $p, q \in [(n-1)/2, n-1]$ and $p + q = n + k - 1$.

\(iii\) The following statements are equivalent:
(a) $\max \{ v_g(S), v_0(S) \} = k$.

(b) $n + k$ is odd, $S_1 = g^k(2g)^{(n-k-1)/2}$ and $S_2 = 0^k(-g)^{(n-k-1)/2}$.

4. If $k \geq \frac{n+1}{2}$, then $h(S) = \max \{ v_g(S), v_0(S) \}$.

Proof. Let $S' = S_1 | S_2$ be a zero-sum subsequence of $S$ where $S_1 \parallel S_1$ and $S_2 \parallel S_2$. We set

$$S'_1 = (a_1 g) \cdots (a_r g) \quad \text{and} \quad S'_2 = (b_1 g) \cdots (b_s g)$$

where $r, s \in \mathbb{N}_0$ and $a_1, \ldots, a_r, b_1, \ldots, b_s \in [1, n]$. Since $S'$ has sum zero, we infer that $\sum_{j=1}^r a_i \equiv \sum_{j=1}^s b_j \pmod{n}$. Since $S'$ has sum zero, we infer that $\sum_{j=1}^r a_i \leq n|S'_1|_g < n$ and

$$0 \leq \sum_{j=1}^r (n - b_j) \leq n||g - S'_2||_g - |S_2| < n - |S_2| \leq n,$$

we infer that $r \leq \sum_{j=1}^r a_i = \sum_{j=1}^r (n - b_j) < n - |S_2|$ and hence $|S'| = |S'_1|_g \leq r + |S_2| < n$.

2. Since $|S_1S_2| = n + k - 1$, $|S_1| \leq n||S'_1|_g < n$ and $|S_2| = |g - S_2| \leq n||g - S'_2||_g < n$, we obtain the first two inequalities. We set

$$M = \max \{ a \in [1, n] \mid \langle ag \rangle \parallel S_1 \} + \max \{ n - b + 1 \mid b \in [1, n], \langle bg \rangle \parallel S_2 \}.$$

Then

$$2(n - 1) \geq n||S'_1|_g + n||g - S'_2||_g \geq M + ([|S_1| - 1] + (|S_2| - 1) \geq M + n - k - 3,$$

and hence $M \leq n - k + 1$. If $a, b \in [1, n]$ such that $\langle ag \rangle \parallel S_1$ and $\langle bg \rangle \parallel S_2$, then $a + n - b + 1 \leq M \leq n - k + 1$ and hence $b - a \geq k$.

3. Since $||S'_1|_g < 1$, we get $0 \parallel S_1$ and thus $v_0(S) = v_0(S_2)$. Similarly, we get $v_g(S) = v_g(S_1)$. We have

$$n - 1 \geq n||S'_1|_g \geq v_g(S_1) + 2(|S_1| - v_g(S_1)) = 2|S_1| - v_g(S_1)$$

and

$$n - 1 \geq n||g - S'_2||_g \geq v_0(S_2) + 2(|S_2| - v_0(S_2)) = 2|S_2| - v_0(S_2).$$

Adding these two inequalities we obtain

$$(*) \quad 2(n - 1) \geq 2|S_1| - (v_g(S) + v_0(S)) = 2(n + k - 1) - (v_g(S) + v_0(S))$$

and hence $v_g(S) + v_0(S) \geq 2k$. Using 2., we get $k \leq \max \{ v_g(S), v_0(S) \} \leq n - 1$ and thus $\min \{ v_g(S), v_0(S) \} \geq 2k - n + 1$.

3. (ii) The implication (b) $\Rightarrow$ (a) is obvious, and hence it suffices to show that (a) $\Rightarrow$ (b).

The equality $v_g(S) + v_0(S) = 2k$ holds if and only if $n - 1 = 2|S_1| - v_g(S)$ and $n - 1 = 2|S_2| - v_0(S)$. These conditions imply that $S_1 = g^{v_g(S)}(2g)^{v_g(S)}$, $S_2 = g^{v_0(S)}(-g)^{v_0(S)}$, and $v_g(S) = 2|S_1| - n + 1 \geq 0$ and $v_0(S) = 2|S_2| - n + 1 \geq 0$. Using 2. we infer that $|S_i| \in [n - 1/2]$, $n - 1$ for $i \in \{1, 2\}$. Now setting $p = |S_1|$ and $q = |S_2|$ we obtain the assertion.

3. (iii) Again it suffices to show that (a) $\Rightarrow$ (b). Suppose that $\max \{ v_g(S), v_0(S) \} = k$. Since $v_g(S) + v_0(S) \geq 2k$, it follows that $v_g(S) = v_0(S) = k$. Thus we have again equality in (a) and in the two previous inequalities, which implies the assertion.

4. Since $v_g(S) + v_0(S) \geq 2k$ and $k \geq \frac{n+1}{2}$, it follows that

$$|g^{2-v_0(S)0-v_0(S)}| \leq |S| - 2k = n - 1 - k \leq k.$$
Proof. 1. We set \( S = g^\nu(S)(a_1g) \ldots (a_kg) \) where \( k \in \mathbb{N}_0 \) and \( a_1, \ldots, a_k \in [2, n] \). Since \( 2(\nu_y(S) + k) = 2[S > n||S||_g] = \nu_y(S) + a_1 + \ldots + a_k \), it follows that

\[
0 < 2[S > n||S||_g] = 2[S] - (\nu_y(S) + a_1 + \ldots + a_k) = \nu_y(S) - \sum_{i=1}^{k} (a_i - 2) \leq \nu_y(S).
\]

2. We start with the following assertion.

**A.** Let \( k \in \mathbb{N} \) and \( 1 = a_0, a_1, \ldots, a_k \in \mathbb{N} \) such that \( a_1 + \ldots + a_i \leq 2i \) for all \( i \in [1, k] \). Then

\[
\left\{ \sum_{i \in I} a_i \mid \emptyset \neq I \subset [0, k] \right\} = \left[ 1, \sum_{i=0}^{k} a_i \right].
\]

**Proof of A.** We proceed by induction on \( k \). If \( k = 1 \), then \( a_1 \leq 2 \), and hence the assertion follows. Suppose that \( k \geq 2 \) and that the assertion holds for \( k - 1 \). Then

\[
\left\{ \sum_{i \in I} a_i \mid \emptyset \neq I \subset [0, k] \right\} = \left\{ \sum_{i \in I} a_i \mid \emptyset \neq I \subset [0, k - 1] \right\} \cup \{a_k\} \cup \left\{ \sum_{i \in I} a_i \mid \emptyset \neq I \subset [0, k - 1] \right\} = \left[ 1, \sum_{i=0}^{k-1} a_i \right] \cup \{a_k\} \cup \left[ 1 + \sum_{i=0}^{k} a_i \right].
\]

Since \( 2 \sum_{i=0}^{k-1} a_i \geq 2k \geq a_1 + \ldots + a_k \), we infer that \( a_k \leq 1 + \sum_{i=0}^{k-1} a_i \), and thus A follows.

We set \( m = 2[S > n||S||_g] \) and \( S = g^m(a_1g) \ldots (a_{|S|-m}g) \) where \( 1 \leq a_1 \leq \ldots \leq a_{|S|-m} \leq n \). Then

\[
a_1 + \ldots + a_{|S|-m} = n||S||_g - m = 2(\nu_y(S) - m) \quad \text{and hence}
\]

\[
a_1 \leq \frac{a_1 + a_2 + \ldots + a_{|S|-m}}{3} \leq \frac{a_1 + a_2 + \ldots + a_{|S|-m}}{|S| - m} = 2,
\]

which implies that \( a_1 + \ldots + a_i \leq 2i \) for all \( i \in [1, |S| - m] \). Let \( x \in [2[S] - n||S||_g, n||S||_g] = [m, 2[S] - m] \) and set \( y = x - (m - 1) \in [1, 2(|S| - m) + 1] \). Then A implies that the sequence \( g(a_1g) \ldots (a_{|S|-m}g) \) has a subsequence \( S' \) with \( \sigma(S') = yy \). Then \( S' = g^{m-1}S' \) is a subsequence of \( S \) with \( |S'| \geq m \) such that \( \sigma(S') = xg \).

Let \( \exp(G) = n \) and \( S \in \mathcal{F}(G) \). Obviously, \( S \) has no zero-sum subsequence of length \( n \) if and only if \( \neg g + S \) has no zero-sum subsequence of length \( n \) for any \( g \in G \). Thus the investigation of sequences, that have no zero-sum subsequences of length \( n \), can be restricted to those sequences \( T \) with \( h(T) = \nu_0(T) \).

**Theorem 7.16 (Savchev-Chen).** Let \( G \) be cyclic of order \( n \geq 3 \) and \( S \in \mathcal{F}(G) \) a sequence of length \( |S| \geq \frac{3n-1}{2} \). Then the following statements are equivalent:

(a) \( S \) has no zero-sum subsequence of length \( n \) and \( b(S) = \nu_0(S) \).

(b) \( S = S_1S_2 \) where \( S_1, S_2 \in \mathcal{F}(G) \) with \( ||S_1||_g < 1 \) and \( ||g - S_2||_g < 1 \) for some \( g \in G \) with \( \text{ord}(g) = n \).

**Proof.** (a) \(\rightarrow\) (b) We set \( S = 0^{\nu(S)}S' \) with \( S' \in \mathcal{F}(G) \). Then (a) and the in particular statement of Proposition 7.13 imply that for every zero-sum subsequence \( T \) of \( S \) we have \( |T| < n \). In particular, \( \nu_0(S) < n \).

Let \( T \) be a zero-sum subsequence of \( S' \) of maximal length. Thus \( U = T^{-1}S' \) is zero-sum free, \( |U| \geq \frac{3n-1}{2} - (n - 1) = \frac{n+1}{2} \). By Theorem 7.81, there is some \( g \in G \) with \( \text{ord}(g) = n \) such that \( U \) is \( g \)-smooth. We set

\[
T = g^{\nu(S)}(b_1g) \ldots (b_qg)
\]

where \( q \in \mathbb{N}_0 \) and \( b_1, \ldots, b_q \in [2, n - 1] \). We continue with the following two assertions.
A1. Let $I \subset [1, q]$ such that $\varphi = n - \sum_{i \in I} (n - b_i) \in [2, n||U||_g]$. Then

$$|I| \le \begin{cases} 2|U| - n||U||_g, & \text{if } \varphi \in [2|U| - n||U||_g, n||U||_g], \\ n||U||_g - 1, & \text{if } \varphi \in [2, 2|U| - n||U||_g - 1]. \end{cases}$$

and $b_i > n||U||_g$ for all $i \in [1, q]$.

A2. $n||U||_g + \sum_{j=1}^{q}(n - b_j) < n$.

Suppose that A2 holds. We set

$$S_1 = g^x(u(T)) \quad \text{and} \quad S_2 = 0^{\text{st}(S)}(b_1g) \ldots (b_qg),$$

and then clearly $S = S_1S_2$. Since $T$ has sum zero, we get $v_g(T) \equiv \sum_{j=1}^{q}(n - b_j)$ mod $n$. Because $S$ has no zero-sum subsequence of length $n$, we have $v_g(T) \in [0, n - 1]$, and by A2 we have $\sum_{j=1}^{q}(n - b_j) < n$.

Thus $v_g(T) = \sum_{j=1}^{q}(n - b_j)$, and again by A2 we infer that $n||S_1||_g = v_g(T) + n||U||_g < n$. Furthermore, it follows that

$$n||g - S_2||_g = \sum_{j=1}^{q}(n - b_j) + (v_0(S) + q) = v_g(T) + h(S) + q = |T| + h(S) < n.$$

Proof of A1. Note that $2|U| - n||U||_g \ge 2|U| - (n - 1) \ge 2$.

Let $\varphi \in [2|U| - n||U||_g, n||U||_g] \subset [2, n - 1]$. By Lemma 7.15.2 there is a subsequence $U'$ of $U$ with $|U'| \ge 2|U| - n||U||_g$, and $\sigma(U') = \varphi g = \left(\sum_{i \in I} (b_i)g\right)$. This implies that $|I'| \ge |U'| \ge 2|U| - n||U||_g$, because $|I| < |U'|$ and replacing $\prod_{i \in I}(b_i)$ by $U'$ would yield a zero-sum subsequence $T'$ of $S$ with $|T'| > |T|$, a contradiction to the maximality of $|T|$.

Let $\varphi \in [2, 2|U| - n||U||_g - 1]$. By Lemma 7.15.1 there is a subsequence $U' = g^x$ of $U$ with $\sigma(U') = \varphi g = \left(\sum_{i \in I} (b_i)g\right)$. As above it follows that $|I| \ge |U'| = \varphi$.

Let $i \in [1, q]$ and assume to the contrary that $b_i \le n||U||_g$. Then $2 \le b_i = n - (n - b_i) \le n||U||_g$, which yields a contradiction to the lower bound of $|I|$ for $I = \{i\}$.

Proof of A2. If $q = 0$, then the assertion follows because $U$ is $g$-smooth. Assume to the contrary that $q \ge 1$ and $n||U||_g + \sum_{j=1}^{q}(n - b_j) \ge n$. Thus there is some minimal $I \subset [1, q]$, say $I = [1, m]$, such that $\varphi = n - \sum_{j=1}^{m}(n - b_j) \le n||U||_g$, and hence $\varphi + (n - b_j) > n||U||_g$ for all $j \in [1, m]$. Since $b_m > n||U||_g$ by A1, we get

$$\varphi > n||U||_g - (n - b_m) > n||U||_g - (n - n||U||_g) = 2n||U||_g - n \ge 2|U| - n \ge 1.$$ 

If $\varphi \in [2|U| - n||U||_g, n||U||_g]$, then A1 implies $m \ge 2|U| - n||U||_g$ and hence

$$n||U||_g + 1 \le n - \sum_{j=1}^{m}(n - b_j) \le n - (m - 1) \le n - (2|U| - n||U||_g - 1) = (n - 2|U| + n||U||_g + 1,$

a contradiction to $2|U| \ge n + 1$.

Suppose that $\varphi \in [2, 2|U| - n||U||_g - 1]$. Then A1 implies $m \ge \varphi$, and since $n - b_j \ge n||U||_g + 1 - \varphi > 0$ for all $j \in [1, m]$, we infer that

$$n = \varphi + \sum_{j=1}^{m}(n - b_j) \ge \varphi + m(n||U||_g + 1 - \varphi) \ge \varphi + \varphi(n||U||_g + 1 - \varphi) = \varphi(n||U||_g + 2 - \varphi).$$

Consider the quadratic function $f : \mathbb{R} \to \mathbb{R}$, defined by $f(x) = x^2 - (n||U||_g + 2)x + n$ for all $x \in \mathbb{R}$, and observe that the above inequality states that $f(\varphi) \ge 0$. However, the maximum value of $f$ in the interval between 2 and $2|U| - n||U||_g - 1$ equals $f(2) = n - 2n||U||_g \le n - 2|U| < 0$, a contradiction.

(b) ⇒ (a) This follows from Proposition 7.14. \qed
Remarks 7.17. Let \( G \) be cyclic of order \( n \geq 3 \).

1. Let \( S \in \mathcal{F}(G) \) be a sequence of length \( n+k-1 \), with \( k \in [(n+1)/2, n-1] \), that has no zero-sum subsequence of length \( n \), and suppose that \( h(S) = v_0(S) \). Then Theorem 7.16 and Proposition 7.14 give structural information on \( S \). In particular, we get \( v_2(S) + v_0(S) \geq 2k \). Thus if \( k = n-1 \), we obtain the description of \( S \) given in Proposition 7.12.

2. We give an example of a sequence \( S \) of length \( |S| = [(3n-2)/2] \), that has no zero-sum subsequence of length \( n \), but that does not satisfy the structural description given in Theorem 7.16.(b). For an element \( h \in G \) with \( \text{ord}(h) = n \), where \( n \geq 9 \) for odd \( n \) and \( n \geq 6 \) for even \( n \), we set

\[
S = \begin{cases} 
0^{n-1}(2h) \frac{n-1}{2}(3h) & \text{if } n \text{ is even}, \\
0^{n-1}(2h) \frac{n-2}{2}(3h)^2 & \text{if } n \text{ is odd}.
\end{cases}
\]

Obviously, \( S \) has the asserted length and no zero-sum subsequence of length \( n \). Assume to the contrary that there exists an element \( g \in G \) with \( \text{ord}(g) = n \) such that the condition in Theorem 7.16.(b) holds. Then Proposition 7.14.4 implies that \( n-1 = h(S) = \max\{v_2(S), v_0(S)\} \), and hence \( S_2 = 0^{n-1} \). Then \( S_1 = S^{-1}S \) and \( ||S||_g \geq 1 \), a contradiction.

7.B Groups of higher rank

We focus on groups of the form \( G = C_r^n \), with \( n, r \in \mathbb{N} \) and \( n \geq 2 \), and start our discussion with the following two properties.

**Property C.** Every sequence \( S \) over \( G \) of length \( |S| = \eta(G) - 1 \) that has no zero-sum subsequence of length in \([1, n]\) has the form \( S = T^n \) for some sequence \( T \) over \( G \).

**Property D.** Every sequence \( S \) over \( G \) of length \( |S| = s(G) - 1 \) that has no zero-sum subsequence of length \( n \) has the form \( S = T^{n-1} \) for some sequence \( T \) over \( G \).

For groups of rank two, Property C was first considered by P. van Emde Boas and Property D by W. Gao (see [30, 45], [44, Lemma 4.7]).

If \( r = 1 \), then \( G \) has Property D by Proposition 7.12. It follows from the very definition that \( C_r^n \) satisfies Property D, and a straightforward argument shows that \( C_r^n \) satisfies Property D (see [28, Lemma 2.3.3] and the subsequent discussion). In [51, Conjecture 7.2] it is conjectured that every group \( G = C_r^n \), where \( r \in \mathbb{N} \) and \( n \in \mathbb{N}_{\geq 2} \), has Property D (see [129, 57]). Groups of rank two will be considered in some detail below.

Following [47, Proposition 2.7] and [64], we work out the relationship between Property C and Property D. We need the technical Property D1 for an (arbitrary group \( G \)) with \( \exp(G) = n \).

**Property D1.** Every sequence \( S \) over \( G \) of length \( |S| = s(G) - 1 \) that has no zero-sum subsequence of length \( n \) satisfies \( h(S) \geq \lfloor \frac{n-1}{2} \rfloor \).

Lemma 7.18. Let \( \exp(G) = n \) and \( S \in \mathcal{F}(G) \).

1. If \( g \in G \) with \( v_g(S) \geq \lfloor \frac{n-1}{2} \rfloor \) and \( S \) has no zero-sum subsequence of length \( n \), then \( S \) has a subsequence \( T \) of length \( |T| \geq |S| - n + 1 \) such that \(-g + T \) has no short zero-sum subsequence.
2. If \( i \in [1, (n+2)/2] \) and \( |S| = \eta(G) + i - 1 \), then \( S \) has a zero-sum subsequence \( T \) of length \( |T| \in [i, n] \).
3. If \( |S| = \eta(G) + n - 1 \) and \( h(S) \geq \lfloor \frac{n-1}{2} \rfloor \), then \( S \) has a zero-sum subsequence of length \( n \).
4. If \( G \) has Property D1, then \( s(G) = \eta(G) + n - 1 \).

**Proof.**

1. Without restriction we may suppose that \( g = 0 \), say \( S = 0^rR \) with \( r \geq \lfloor \frac{n-1}{2} \rfloor \) and \( R \in \mathcal{F}(G) \). Let \( U \) be a zero-sum subsequence of \( R \) such that \( |U| \leq n \) is maximal. Then, by the maximality of \( |U| \), either \( |U| > n/2 \) or \( U^{-1}R \) has no short zero-sum subsequence. Since \( S \) has no zero-sum subsequence of
length $n$, it follows that $|U| + v < n$. Thus $|U| \leq n/2$ and $T = U^{-1}R$ has no short zero-sum subsequence. Since $|S| = |T| + |U| + v$ and $|U| + v < n$, we obtain that $|T| > |S| - n$.

2. We proceed by induction on $i$. For $i = 1$, the assertion is clear. Now suppose the assertion holds for $i \in [1, n/2]$, and we have to show it for $i + 1$. Then $S$ has a zero-sum subsequence $T_1$ of length $|T_1| \in [i, n]$. If $|T_1| = i + 1$, then we are done. Otherwise, $|T_1| = i$ and $|T_1^{-1}S| \geq \eta(G)$. Thus $T_1^{-1}S$ has a short zero-sum subsequence $T_2$. If $|T_2| \geq i + 1$, then we are done. Otherwise, $|T_2| \in [1, i]$ and $T_1T_2$ is a zero-sum subsequence of $S$ of length $1 + i \leq |T_1T_2| \leq 2i \leq n$.

3. We may suppose that $S = 0^v R$ with $v \geq \lceil \frac{n-1}{2} \rceil$ and $R \in F(G)$, if $v \geq n$, then we are done. Suppose that $v < n - 1$. Since $|R| = \eta(G) + n - 1 - v$ and $1 \leq n - v \leq (n + 2)/2$, implies that $R$ has a zero-sum subsequence $T$ of length $|T| \in [n - v, n]$. Thus $0^v R \backslash |T| T$ is a zero-sum subsequence of $S$ of length $n$.

4. Lemma 6.5.1 implies that $s(G) \geq \eta(G) + n - 1$. Let $S \in F(G)$ be a sequence of length $|S| = s(G) - 1$ that has no zero-sum subsequence of length $n$. By Property D1 we have $h(S) \geq \lceil \frac{n-1}{2} \rceil$, and hence 3. implies that $s(G) - 1 = |S| \leq \eta(G) + n - 2$. □

Proposition 7.19. Let $G = C^r_n$ with $r, n \geq 2$. Then the following statements are equivalent:

(a) $G$ has Property D.
(b) $G$ has Properties C and D1.

Proof. (a) ⇒ (b) By definition, $G$ has Property D1. To show that $G$ satisfies Property C as well, let $S \in F(G)$ be a sequence of length $\eta(G) - 1$ which has no short zero-sum subsequence. We consider the sequence

$$T = 0^{n-1} S.$$ 

If $T$ has a zero-sum subsequence $T'$ of length $|T'| = n$, then $T' = 0^k S'$ with $k \in [0, n-1]$ whence $S'$ is a short zero-sum subsequence of $S$. Since Property D holds, Lemma 7.18.4 implies that $|T| = \eta(G) - 1 + (n - 1) = s(G) - 1$. Therefore Property D implies that $S$ has the required form.

(b) ⇒ (a) Let $S \in F(G)$ be a sequence of length $|S| = s(G) - 1$ that has no zero-sum subsequence of length $n$. By Property D1, $S$ may be written in the form $S = g^{h(S)} S'$ where $g \in G, S' \in F(G)$ and $h(S) \geq \lceil \frac{n-1}{2} \rceil$. By Lemma 7.18.1, $S$ has a subsequence $T$ of length $|T| \geq |S| - n + 1 \geq \eta(G) - 1$ such that $-g + T$ has no short zero-sum subsequence. Clearly, we may suppose that $|T| = \eta(G) - 1$. Since $G$ has Property C, it follows that there are $a_1, \ldots, a_k \in G$ such that $-g + T = (a_1 \cdot \ldots \cdot a_k)^{n-1}$. Since $0 \notin \{a_1, \ldots, a_k\}$, it follows that $T | S'$. This implies that $h(S) = n - 1$ and hence $S = (g(g + a_1) \cdot \ldots \cdot (g + a_k))^{n-1}$. □

Suppose that Property D holds. Then, by definition, there exists some $c(G) \in N$ such that $s(G) = c(G)(n - 1) + 1$. For $r = 1$ we have $c(G) = 2$ and for $r = 2$ we have $c(G) = 4$ (see Theorem 6.13). In case of higher ranks bounds for $c(G)$ are given by N. Alon and M. Dubiner ([2]) and then in [100, 29, 28, 27].

Property C and Property D are both multiplicative, provided that the $c(\cdot)$-invariants of all involved groups coincide (see [56, Theorem 3.2]).

Theorem 7.20. Let $G = C^r_m$ with $m, n, r \in N$.

1. If both $C^r_m$ and $C^r_n$ have Property D and

$$\frac{s(C^r_m) - 1}{m - 1} = \frac{s(C^r_n) - 1}{n - 1} = \frac{s(C^r_m) - 1}{mn - 1},$$

then $G$ has Property D.

2. If both $C^r_m$ and $C^r_n$ have Property C and

$$\frac{\eta(C^r_m) - 1}{m - 1} = \frac{\eta(C^r_n) - 1}{n - 1} = \frac{\eta(C^r_m) - 1}{mn - 1},$$

then $G$ has Property C.
Lemma 7.21. Let work this out we need some preparations.

Property B. Every minimal zero-sum sequence \( S \) over \( G \) of length \( |S| = D(G) = 2n - 1 \) contains some element with multiplicity \( n - 1 \).

It is conjectured that every group of the above form satisfies Property B. Several equivalent conditions to Property B may be found in [71, Section 5.8]. Proposition 7.23 shows that if \( G \) satisfies one of the Properties B, C or D, then the structure of the extremal sequences is completely determined. In order to work this out we need some preparations.

**Lemma 7.21.** Let \( G = C_n \oplus C_n \) with \( n \geq 2 \) and \( S \in F(G) \). If \( |S| = 3n - 3 \) and \( S \) has no short zero-sum subsequence, then \( S \) has a minimal zero-sum subsequence \( T \) of length \( |T| = 2n - 1 \).

**Proof.** Suppose that \( |S| = 3n - 3 \), that \( S \) has no short zero-sum subsequence and set \( W = 0S \in F(G) \).

Then Corollary 6.14 implies that \( W \) has a zero-sum subsequence \( U \) of length \( |U| \in \{n, 2n\} \), and by our assumption on \( S \) we get \( |U| = 2n \). If \( U \) is a subsequence of \( S \), then \( D(G) = 2n - 1 \) implies that \( U = U_1U_2 \), where both \( U_1 \) and \( U_2 \) are non-trivial zero-sum sequences. Therefore, either \( U_1 \) or \( U_2 \) is a short zero-sum subsequence of \( S \), a contradiction. Therefore, \( U = 0T \) with \( |T| = 2n - 1 \), and since \( S \) has no short zero-sum subsequence, it follows that \( T \) is a minimal zero-sum sequence. \( \square \)

**Theorem 7.22.** Let \( G = C_n \oplus C_n \) with \( n \geq 2 \) and let \( S \in A(G) \) be a minimal zero-sum sequence of length \( |S| = 2n - 1 \).

1. For every \( g \in \text{supp}(S) \) we have \( \text{ord}(g) = n \).
2. If \( |\text{supp}(S)| = 3 \), then \( S \) contains some element with multiplicity \( n - 1 \).
3. If \( G \) has Property B, then \( G \) has Property C.

**Proof.**
1. See [71, Theorem 5.8.4]. The proof is done by the inductive method.
2. See [101, Theorem 1]. The proof uses the theory of continued fractions.
3. By Corollary 6.14 this follows from [49, Theorem 6.2]. \( \square \)

**Proposition 7.23.** Let \( G = C_n \oplus C_n \) with \( n \geq 2 \) and let \( S \in F(G) \).

1. If \( S \) has length \( D(G) \), then the following statements are equivalent:
   a. \( S \) is a minimal zero-sum sequence and contains some element with multiplicity \( n - 1 \).
   b. There exists a basis \( \{e_1, e_2\} \) of \( G \) and integers \( x_1, \ldots, x_n \in [0, n - 1] \) with \( x_1 + \ldots + x_n \equiv 1 \mod n \) such that
      \[
      S = e_1^{n-1} \prod_{i=1}^{n} (x_i e_1 + e_2).
      \]
2. If \( S \) has length \( \eta(G) - 1 \), then the following statements are equivalent:
   a. \( S = T^{n-1} \) for some \( T \in F(G) \) and \( S \) has no short zero-sum subsequence.
   b. There exists a basis \( \{e_1, e_2\} \) of \( G \) and some \( x \in [1, n - 1] \) with \( \gcd(x, n) = 1 \) such that
      \[
      S = (e_1e_2(xe_1 + e_2))^{n-1}.
      \]
3. If \( S \) has length \( s(G) - 1 \), then the following statements are equivalent:
   a. \( S = T^{n-1} \) for some \( T \in F(G) \) and \( S \) has no zero-sum subsequence of length \( n \).
   b. For every \( g \in \text{supp}(S) \) there exists a basis \( \{e_1, e_2\} \) of \( G \) and some \( x \in [1, n - 1] \) with \( \gcd(x, n) = 1 \) such that
      \[
      -g + S = (0e_1e_2(xe_1 + e_2))^{n-1}.
      \]
Proof. In all three items, the implications (b) $\Rightarrow$ (a) are obvious. Thus it remains to verify the converse.

1. Let $S = e_1 e_2 \cdots e_n g_1 \cdots g_n$, where $g_1, \ldots, g_n \in G$. Then $\text{ord}(e_1) = n$, and there exists some $\hat{c} \in G$ such that $(e_1, \hat{c})$ is a basis of $G$. For $i \in [1, n]$ let $x_i, y_i \in [0, n-1]$ be such that $y_i = x_i e_1 + y_i \hat{c}$. Since

$$\sigma(S) = (n-1 + x_1 + \cdots + x_n)e_1 + (y_1 + \cdots + y_n)\hat{c} = 0,$$

we obtain that $x_1 + \cdots + x_n \equiv 1 \mod n$, and that $B = (y_1 \hat{c}) \cdots (y_n \hat{c})$ has sum zero. We assert that $B$ is even a minimal zero-sum sequence. Indeed, otherwise there exists some $k_0 \neq I \subseteq [1, n]$ such that

$$\sum_{i \in k_0} y_i \equiv 0 \mod n.$$

If $k \in [0, n-1]$ is such that

$$\sum_{i \in k} x_i \equiv n - k \mod n, \quad \text{then} \quad e_1^k \prod_{i \in k} (x_i e_1 + y_i \hat{c})$$

has sum zero, a contradiction to $S \in \mathcal{A}(G)$. Now Corollary 4.4.1 implies that $y_1 = \ldots = y_n = y$, where $\text{gcd}(y, n) = 1$, and we set $e_2 = y \hat{c}$ to complete the proof.

2. Let $S = T^{n-1}$ be as in 2.(a). By Lemma 7.21, $S$ has a minimal zero-sum subsequence $U$ of length $|U| = 2n - 1$. Since $3 = |\text{supp}(S)| = |\text{supp}(U)|$, Theorem 7.22.2 and item 1. imply that $U$ has a form as given in 1(b). Thus there exists a basis $(e_1, e_2)$ of $G$ such that $T = e_1(x_1 e_1 + e_2)(x_2 e_1 + e_2)$ with $0 \leq x_1 < x_2 < n - 1$. Clearly, $(f_1, f_2) = (e_1, x_1 e_1 + e_2)$ is a basis of $G$ and hence $T = f_1 f_2(x f_1 + f_2)$ with $x \in [1, n-1]$. Assume the contrary, that $\text{gcd}(x, n) = a > 1$ and set $n' = n/a$. Then $(x f_1 + f_2)^{m/n'} f_2^{n-n'}$ is a short zero-sum subsequence of $S$, a contradiction.

3. Let $S = T^{n-1}$ be as in 3.(a) and let $g \in \text{supp}(S)$. Then $T = g U$ for some $U \in \mathcal{F}(G)$. Since $-g + U^{n-1}$ has no short zero-sum subsequence, 2. implies that $-g + S$ has the required form. \hfill $\square$

The argument in Proposition 7.23.2 stems from [120]. Moreover, in that paper Wolfgang A. Schmid established a characterization of the structure of all minimal zero-sum sequences over $C_{n_1} \oplus C_{n_2}$, where $1 < n_1 \mid n_2$, of length $\text{D}(C_{n_1} \oplus C_{n_2}) = n_1 + n_2 - 1$, under the hypothesis that $C_{n_1} \oplus C_{n_1}$ has Property B. Analogous results were derived for Properties C and D.

The next theorem reduces the question whether Property B holds for all groups under discussion to groups $C_p \oplus C_p$ where $p$ is a prime (see [54]). Property B is verified for some small primes in [49, 5].

Theorem 7.24. Let $G = C_n \oplus C_n$ with $n \geq 2$. If for every prime divisor $p$ of $n$ the group $C_p \oplus C_p$ has Property B, then $G$ has Property B.

Theorem 7.25. Let $G = C_p \oplus C_p$ for some odd prime $p$ and let $S \in \mathcal{F}(G)$.

1. If $S$ is a minimal zero-sum sequence of length $|S| = \text{D}(G)$, then $|\text{supp}(S)| \in [3, p]$.

2. If $S$ is zero-sum free of length $\text{D}(G) - 1$, then each two distinct elements of $\text{supp}(S)$ are independent.

3. If $S$ is zero-sum free of length $\text{D}(G) - 1$, $\varepsilon > 0$ and $p$ sufficiently large, then $S$ contains some element $g$ with multiplicity $v_g(S) > p^{1/4 - \varepsilon}$.

Proof. 1. See [71, Proposition 5.8.5]. Note that for every $j \in [3, p]$ there is an $S_j \in \mathcal{A}(G)$ of length $|S_j| = \text{D}(G)$ and with $|\text{supp}(S_j)| = j$.

2. See [71, Corollary 5.6.9]. The proof is based on a covering result.

3. See [56, Theorem 4.1]. The proof is based on a Theorem of J.A. Dias da Silva and Y. ould Hamidoune ([21]) which runs as follows: if $A \in \mathcal{F}(G)$ is a squarefree sequence and $k \in [1, |A|]$, then

$$|\Sigma_k(A)| \geq \min \{p, k(|A| - k) + 1\}.$$
7.C Arithmetical consequences

Some simple arithmetical consequences of Property B can be found in [71, Chapter 6]. In this subsection we restrict to cyclic groups and start with a result, first proved in [53] and based on Theorem 7.8.

Theorem 7.26. Let $H$ be a Krull monoid with cyclic class group $G$ of order $n \geq 2$ such that every class contains a prime. Then for every $k \in \mathbb{N}$ we have $\rho_{2k+1}(H) = kn + 1$.

**Proof.** By Theorem 3.16 it suffices to consider $B(G)$. Assume to the contrary that there is some $k \in \mathbb{N}$ such that $\rho_{2k+1}(G) \geq kn + 2$. Let $k \in \mathbb{N}$ be minimal with this property whence $\rho_{2k-1}(G) = (k-1)n + 1$. Thus there are $B \in B(G)$ and $U_1, \ldots, U_{2k+1}, V_1, \ldots, V_\rho \in A(G)$ with $\rho = \rho_{2k+1}(G)$, $|U_i| \geq \ldots \geq |V_{2k+1}|$, $|V_i| \leq \ldots \leq |V_\rho|$ and

\[ B = U_1 \cdots U_{2k+1} = V_1 \cdots V_\rho. \]

We may suppose that $|B|$ is maximal such that an equation (*) holds. Since $\rho_{2k}(G) = kn$, it follows that $0 \notin B$ whenever $|U_{2k+1}| \geq 2$.

Let $\ell \in [0, \rho]$ such that $|V_\ell| = 2$ and $3 \leq |V_{k+1}|$, and assume that (*) is a representation with maximal $\ell$. Then $h(-h) \notin V_{k+1} \cdots V_\rho$ for any $h \in G$. Indeed, assume to the contrary that there are $h \in G$ and distinct $i, j \in [\ell + 1, \rho]$ such that $h | V_i$ and $-h | V_j$. Then $V_iV_j = h(-h)V'$ with $V' \in B(G)$, and by the maximality of $\rho$ it follows that $V' \in A(G)$. But this contradicts the maximal choice of $\ell$.

Next we prove that $\ell \geq 1$. If $\ell = 0$, then $3\rho \leq |B| \leq (2k+1)\rho$ implies $\rho \leq \frac{n}{2}(2k+1) < kn + 1$, a contradiction.

By the maximality of $|B|$ it follows that, for all $i \in [1, 2k+1]$, $U_i$ is not splittable, and we assert that $|U_{2k}| \geq \left[ \frac{n}{2} \right] + 2$. Indeed, assume to the contrary that $|U_{2k}| \leq \left[ \frac{n}{2} \right] + 1$. Then

\[ 2\rho \leq |B| \leq \left( (2k-1)n + 2 \left( \frac{n}{2} + 1 \right) \right) = 2kn + 2, \]

and hence $\rho \leq kn + 1$, a contradiction. Thus Theorem 7.8 implies that $U_i = g_i^n$ for all $i \in [1, 2k]$.

Assume to the contrary that there are $i, j \in [1, 2k+1]$ such that $U_i = g^n$ and $U_j = (-g)^n$. Then $\ell \geq n$, and after renumbering if necessary we may suppose that $V_1 = \ldots = V_n = (-g)g$. Since $(U_iU_j)^{-1}B = V_{n+1} \cdots V_\rho$, it follows that $(k-1)n + 1 = \rho_{2k-1}(G) \geq \rho - n \geq (k-1)n + 2$, a contradiction. Thus there are no two $U_i, U_j$ of such a form and hence $\ell \leq |U_{2k+1}|$.

If $|U_{2k+1}| \geq \left[ \frac{n}{2} \right] + 2$, then Theorem 7.8 implies that $U_{2k+1} = g_{2k+1}^n$ for some $g_{2k+1} \in G$. Since $\ell \geq 1$, it follows that $g_{2k+1} \in \{-g_1, \ldots, -g_{2k}\}$, a contradiction. Thus

\[ |U_{2k+1}| \leq \left[ \frac{n}{2} \right] + 1, \]

and therefore we obtain that

\[ \rho \leq \ell + \frac{|B| - 2\ell}{3} = \frac{|B| + \ell}{3} = \frac{2kn + |U_{2k+1}| + \ell}{3} \leq \frac{2kn + 2|U_{2k+1}|}{3} \leq \frac{2kn + n + 2}{3} \leq kn + \frac{2}{3}, \]

a contradiction. □

Corollary 7.27. Let $H$ be a Krull monoid with cyclic class group $G$ of order $n \geq 2$ such that every class contains a prime. Then for every $k \in \mathbb{N}$ and every $l \in \mathbb{N}_0$ we have $\nu_{k}(H) = [\nu_{k}(H), \rho_{k}(H)]$.

\[ \rho_{k+j}(H) = kn + j \text{ for } j \in [0, 1] \text{ and } \lambda_{n+j}(H) = \begin{cases} 2l + j & \text{for } j \in [0, 1] \\ 2l + 2 & \text{for } j \in [2, n-1] \end{cases} \]

provided that $ln + j \geq 1$. 

50 ALFRED GEHROLDINGER
Proof. As in the proof of Theorem 5.3 it suffices to consider the block monoid \( \mathcal{B}(G) \). If \( n = 2 \), then \( \mathcal{B}(G) \) is half-factorial whence for all \( k \in \mathbb{N} \) we have \( \lambda_k(G) = k = \rho_k(G) \). Suppose that \( n \geq 3 \), and let \( k \in \mathbb{N} \). By Theorem 5.3 we obtain that \( \mathcal{V}_k(H) = [\lambda_k(G), \rho_k(G)] \). The assertion on \( \rho_{2k+j}(G) \) follows from Theorem 7.26, and the assertion on \( \lambda_{N+j}(G) \) follows from Corollary 5.4.

Corollary 7.28. Let \( G \) be either cyclic or an elementary 2-group with Davenport constant \( D(G) = n \geq 4 \). If \( G' \) is a finite abelian group with \( L(G) = L(G') \), then \( G \cong G' \).

Proof. Suppose that \( L(G) = L(G') \). Then Proposition 5.14 implies that \( \Delta(G) = \Delta(G') \) and \( \rho_k(G) = \rho_k(G') \) for all \( k \in \mathbb{N} \). By Corollary 4.16 it follows that \( G' \) is either cyclic or an elementary 2-group. Corollary 5.5 and Theorem 7.26 imply that

\[
 \rho_3(C_n) = n + 1 < \left\lceil \frac{3n}{2} \right\rceil = \rho_3(C_n^2) ,
\]

and thus we obtain that \( G \cong G' \).
