

Four Color theorem for image segmentation

Xue-Cheng Tai, University of Bergen, Norway

Collaborations with:

Xavier Bresson, Tony F. Chan and Ruilinag Zhang

July 17, 2014

The original Mumford-Shah

The Mumford-Shah (MS) model:

$$\min_{C,s} \mu|C| + \frac{\alpha}{2} \int_{\Omega} (s - s_0)^2 + \frac{\gamma}{2} \int_{\Omega \setminus C} |\nabla s|^2, \quad (1)$$

The original Mumford-Shah

The Mumford-Shah (MS) model:

$$\min_{C,s} \mu|C| + \frac{\alpha}{2} \int_{\Omega} (s - s_0)^2 + \frac{\gamma}{2} \int_{\Omega \setminus C} |\nabla s|^2, \quad (1)$$

The piecewise constant Mumford-Shah

The PC Mumford-Shah (MS) model:

$$\min_r \min_{\{\Gamma_i\}_{i=1}^r} \min_{\{c_i\}_{i=1}^r} \sum_{i=1}^r \mu |\partial \Gamma_i| + \frac{\alpha}{2} \int_{\Gamma_i} (c_i - s_0)^2 \text{ s.t.}$$
$$\Omega = \cup_{i=1}^r \Gamma_i \text{ and } \Gamma_i \cap \Gamma_j = \emptyset \forall i \neq j \quad (2)$$

The Potts model

Given $\{f_i\}_{i=1}^n$ for a fixed number n , the Potts model needs to:

$$\min_{\Gamma_i} \sum_{i=1}^n \mu |\partial \Gamma_i| + \int_{\Gamma_i} f_i, \quad \Omega = \cup_{i=1}^n \Gamma_i, \quad \Gamma_i \cap \Gamma_j = \emptyset, \forall i, j.$$

The Potts model

Given $\{f_i\}_{i=1}^n$ for a fixed number n , the Potts model needs to:

$$\min_{\Gamma_i} \sum_{i=1}^n \mu |\partial \Gamma_i| + \int_{\Gamma_i} f_i, \quad \Omega = \cup_{i=1}^n \Gamma_i, \quad \Gamma_i \cap \Gamma_j = \emptyset, \forall i, j.$$

So if the number n and c_i are known, the PC Mumford-Shah is reduced to the Potts model choosing $f_i = |c_i - u_0|^2$.

Combining Mumford-Shah with GAC

It is possible to combine these two popular models together and it has been shown to have superior property with no extra computational cost:

$$\min_{n, \Gamma_i, c_i} \sum_{i=1}^n \int_{\Gamma_i} (u_0 - c_i)^2 + \beta \int_{\partial\Gamma_i} g(|\nabla u_\sigma|) ds$$

Chan-Vese model – One of the most popular segmentation model

Given an input image u_0 , the 2-phase level set representation is find ϕ and c_i from:

$$\min_{\Gamma, c_1, c_2} \alpha |\Gamma| + \int_{\Omega_1} |c_1 - u_0|^2 + \int_{\Omega_2} |c_2 - u_0|^2.$$

Chan-Vese model – One of the most popular segmentation model

Given an input image u_0 , the 2-phase level set representation is find ϕ and c_i from:

$$\min_{\Gamma, c_1, c_2} \alpha |\Gamma| + \int_{\Omega_1} |c_1 - u_0|^2 + \int_{\Omega_2} |c_2 - u_0|^2.$$

$$\min_{\phi, c_1, c_2} \int_{\Omega} \alpha |\nabla H(\phi)| + \{H(\phi)(c_1 - u_0)^2 + (1 - H(\phi))(c_2 - u_0)^2\} dx,$$

Chan-Vese model – One of the most popular segmentation model

Given an input image u_0 , the 2-phase level set representation is find ϕ and c_i from:

$$\min_{\Gamma, c_1, c_2} \alpha |\Gamma| + \int_{\Omega_1} |c_1 - u_0|^2 + \int_{\Omega_2} |c_2 - u_0|^2.$$

$$\min_{\phi, c_1, c_2} \int_{\Omega} \alpha |\nabla H(\phi)| + \{H(\phi)(c_1 - u_0)^2 + (1 - H(\phi))(c_2 - u_0)^2\} dx,$$

- ▶ $H(\phi) = 1$ if $\phi > 0$, $H(\phi) = 0$ if $\phi < 0$
- ▶ From ϕ , we get $\Omega_1 = \{x | \phi > 0\}$, $\Omega_2 = \{x | \phi \leq 0\}$.

More than two regions—multiple level-sets (Chan and Vese, 2000)

$$\Omega_{++} = \{x \in \Omega, \phi_1 > 0, \phi_2 > 0\}$$

$$\Omega_{+-} = \{x \in \Omega, \phi_1 > 0, \phi_2 < 0\}$$

$$\Omega_{-+} = \{x \in \Omega, \phi_1 < 0, \phi_2 > 0\}$$

$$\Omega_{--} = \{x \in \Omega, \phi_1 < 0, \phi_2 < 0\}.$$

Multiphase level set representation of CV model

$$\min_{\phi^1, \phi^2, \{c_i\}_{i=1}^4} \alpha \int_{\Omega} |\nabla H(\phi^1)| + \alpha \int_{\Omega} |\nabla H(\phi^2)| + E^{data}(\phi^1, \phi^2),$$

where

$$E^{data}(\phi^1, \phi^2) = \int_{\Omega} \{H(\phi^1)H(\phi^2)|c_2 - u_0|^\beta + H(\phi^1)(1 - H(\phi^2))|c_1 - u_0|^\beta \\ + (1 - H(\phi^1))H(\phi^2)|c_4 - u_0|^\beta + (1 - H(\phi^1))(1 - H(\phi^2))|c_3 - u_0|^\beta\} dx.$$

$$\Omega_1 = \{x \in \Omega \text{ s.t. } \phi^1(x) > 0, \phi^2(x) < 0\}$$

$$\Omega_2 = \{x \in \Omega \text{ s.t. } \phi^1(x) > 0, \phi^2(x) > 0\}$$

$$\Omega_3 = \{x \in \Omega \text{ s.t. } \phi^1(x) < 0, \phi^2(x) < 0\}$$

$$\Omega_4 = \{x \in \Omega \text{ s.t. } \phi^1(x) < 0, \phi^2(x) > 0\}$$

Chan-Vese model – Advantages

- ▶ Use the level set of Osher and Sethian (JCP1998): can handle very general geometries.
- ▶ Region based: robust with noise, images without edges.

Chan-Vese model – disadvantages

- ▶ Slow in convergence.
- ▶ Each Ω_i can contain many disconnected subregions, we must have $u = c_i$ in Ω_i .

(a) Input images

(b) Segmented image

Chan-Vese model – disadvantages

- ▶ Slow in convergence.
- ▶ Each Ω_i can contain many disconnected subregions, we must have $u = c_i$ in Ω_i .

(a) Input images

(b) Segmented image

- ▶ If u needs to take n constant values, then we need n -phases for the segmentation.

Chan-Vese model – disadvantages

- ▶ Slow in convergence.
- ▶ Each Ω_i can contain many disconnected subregions, we must have $u = c_i$ in Ω_i .

(a) Input images

(b) Segmented image

- ▶ If u needs to take n constant values, then we need n -phases for the segmentation.
- ▶ Our new model allows u to take many constant values inside Ω_i .

Chan-Vese model – disadvantages

- ▶ Need to use many level set functions or labeling functions

(a) Input images

(b) Segmented image (8 phases)

Figure: Our new model never needs more than 4-phases to get the same segmentation.

Chan-Vese model – disadvantages

- ▶ Slow in convergence.
- ▶ Non-convex minimization: may get stuck with local minimums, depends on initial value.

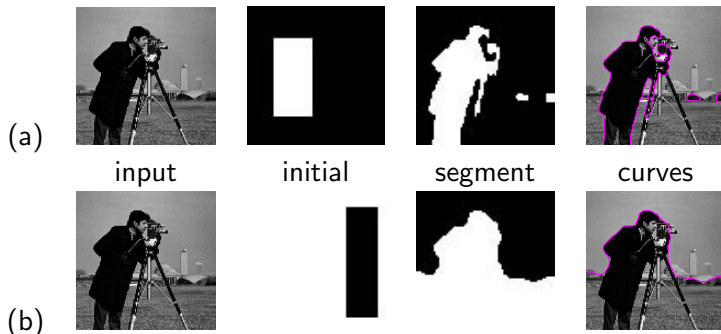

Figure: Images from Brown-Chan-Bresson (IJCV 2011).

The New 4-Color Model Based On Munford-Shah

The new 4-color theorem

Any planar graph (map) can be painted and separated by 4 colors.

The new 4-color model based on Mumford-Shah

The new model: Due to 4-color theorem:

$$\begin{aligned} & \min_{\{\Omega_i\}_{i=1}^4} \min_{\{s_i\}_{i=1}^4} \sum_{i=1}^4 \mu |\partial\Omega_i| + \frac{\alpha}{2} \int_{\Omega_i} (s_i - s_0)^2 \quad \text{s.t.} \\ & \Omega = \cup_{i=1}^4 \Omega_i, \Omega_i \cap \Omega_j = \emptyset \quad \forall i \neq j \\ & \text{and } |\nabla s_i(x)|^2 = 0 \quad \text{in } \Omega_i. \end{aligned} \tag{6}$$

$$s_j : \Omega \mapsto R, j = 1, 2, 3, 4.$$

The new 4-color model based on Munford-Shah

$$\nabla s_j = 0 \text{ in } \Omega_j$$

$$s_j = \text{const in } \Omega_j.$$

The new 4-color model based on Munford-Shah

$$s_j : \Omega \mapsto R,$$

$$\nabla s_j = 0 \text{ in } \Omega_j;$$

$s_j = \text{const}$, but the constants can differ from one connected subregion to another connected subregion.

Regularization of s_j

$$\min_{\{\Omega_i\}_{i=1}^4} \min_{\{s_i\}_{i=1}^4} \sum_{i=1}^4 \mu |\partial\Omega_i| + \frac{\alpha}{2} \int_{\Omega_i} (s_i - s_0)^2 + \frac{\sigma}{2} \int_{\Omega} |\nabla s_i|^2 \quad \text{s.t.}$$
$$\Omega = \cup_{i=1}^4 \Omega_i, \quad \Omega_i \cap \Omega_j = \emptyset \quad \forall i \neq j \quad \text{and} \quad |\nabla s_i(x)|^2 = 0 \quad \text{in } \Omega_i. \quad (7)$$

Adding σ , we regularize the values of s_j outside Ω_j . In fact, the values of s_j is the harmonic extensions of the piecewise constant values of s_j inside Ω_j .

Representation of $\{\Omega_i\}_{i=1}^4$

- ▶ Using level set functions (slow, non-convex).

Representation of $\{\Omega_i\}_{i=1}^4$

- ▶ Using level set functions (slow, non-convex).
- ▶ Using binary labels: $u_1, u_2 \in \{0, 1\}$.

Representation of $\{\Omega_i\}_{i=1}^4$

- ▶ Using level set functions (slow, non-convex).
- ▶ Using binary labels: $u_1, u_2 \in \{0, 1\}$.
- ▶ Using a single label: $u \in \{1, 2, 3, 4\}$.

Representation of $\{\Omega_i\}_{i=1}^4$

- ▶ Using level set functions (slow, non-convex).
- ▶ Using binary labels: $u_1, u_2 \in \{0, 1\}$.
- ▶ Using a single label: $u \in \{1, 2, 3, 4\}$.
- ▶ Using the characteristic function $u_i = \chi_{\Omega_i}$, $i = 1, 2, 3, 4$.

Representation of $\{\Omega_i\}_{i=1}^4$

- ▶ Using level set functions (slow, non-convex).
- ▶ Using binary labels: $u_1, u_2 \in \{0, 1\}$.
- ▶ Using a single label: $u \in \{1, 2, 3, 4\}$.
- ▶ Using the characteristic function $u_i = \chi_{\Omega_i}$, $i = 1, 2, 3, 4$.

All can be convexified and have fast solvers.

Chan-Vese (product) binary labelling

- ▶ Use two binary functions: $u_1, u_2 \in \{0, 1\}$.
- ▶ Corresponding characteristic functions:
 $\psi_1 = u_1 u_2, \psi_2 = (1 - u_1) u_2, \psi_3 = u_1 (1 - u_2), \psi_4 = (1 - u_1)(1 - u_2)$.
- ▶ Convex equivalence exists: Bae-T. (EMMCVPV09), Bae-T. (JMIV 2014), Goldluecke-Cremers ECCV(2010).

- ▶ Use a single labeling functions: $u \in \{1, 2, 3, 4\}$.
- ▶ Corresponding characteristic functions:
 $\psi_i = 1$ when $u = i$, else $\psi_i = 0$.
- ▶ Convex equivalence exists: Ishikawa, Darbon-Segelle, Pock-Bremer-Chambolle-et-al, Bae-T., Brown-Bresson-Chan, Golstein-Bresson-Osher.

Characteristic function labelling

- ▶ Use labeling functions: $u_i \in \{0, 1\}$, $\sum_{i=1}^4 u_i = 1$.
- ▶ Convex equivalence exists: Pock-Cremers-Chambolle-et-al (ICCV 2008, ...), Bae-Yuan-T. (IJCV2010), Lellman-et-al (2010,2011,2012), Zach-et-al (2009).

Characteristic Labelling functions (PCLS)

$$u_i(x) = \begin{cases} 1, & \forall x \in \Omega_i, \\ 0, & \text{otherwise.} \end{cases} \quad (8)$$

The problem (7) can thus be rewritten as

$$\begin{aligned} & \min_{\{u_i \in \{0,1\}\}_{i=1}^4} \min_{\{s_i\}_{i=1}^4} \sum_{i=1}^4 \int_{\Omega} \mu(x) |\nabla u_i| + \frac{\alpha}{2} u_i (s_i - s_0)^2 + \frac{\sigma}{2} |\nabla s_i|^2 \\ & \sum_{i=1}^4 u_i(x) = 1 \quad \forall x \in \Omega \\ & \text{and } u_i(x) |\nabla s_i(x)|^2 = 0 \quad \forall x \in \Omega, i = 1, \dots, 4. \end{aligned} \quad (9)$$

Lagrangian functional

We use Lagrangian method to deal with the constrain. The corresponding Augmented Lagrangian functional is:

$$\begin{aligned} L(\{u_i\}_{i=1}^4, \{s_i\}_{i=1}^4, \lambda) = & \\ & \sum_{i=1}^4 \int_{\Omega} \mu |\nabla u_i| + \frac{\alpha}{2} \int_{\Omega} u_i (s_i - s_0)^2 + \frac{\sigma}{2} \int_{\Omega} |\nabla s_i|^2 \\ & + \int_{\Omega} \lambda(x) u_i(x) |\nabla s_i(x)|^2 + \frac{r}{2} u_i(x) |\nabla s_i(x)|^2. \\ & u_i(x) \geq 0, \quad \sum_{i=1}^4 u_i(x) = 1 \quad \forall x \in \Omega \end{aligned} \tag{10}$$

An algorithm

$$\begin{aligned}(u_i^{k+1}, s_i^{k+1}) = \arg \min_{\{u_i \in [0,1]\}_{i=1}^4, \{s_i\}_{i=1}^4} & \sum_{i=1}^4 \int_{\Omega} w_b |\nabla u_i| + \frac{\alpha}{2} \int_{\Omega} u_i (s_i - s_0)^2 \\ & + \frac{\sigma}{2} \int_{\Omega} |\nabla s_i|^2 + \int_{\Omega} u_i (\lambda_i^k |\nabla s_i|^2 + \frac{r}{2} |\nabla s_i|^2) \quad \text{s.t.} \quad \sum_{i=1}^4 u_i(x) = 1. \\ \lambda_i^{k+1} = \lambda_i^k + r u_i |\nabla s_i|^2 & \quad (11)\end{aligned}$$

where $w_b(x)$ can be an edge detector s.a. $w_b(x) = \frac{1}{1+\mu|\nabla s_0(x)|^2}$.

An algorithm: Subproblem I

$$\min_{u_i \in [0,1]} \int_{\Omega} w_b |\nabla u_i| + \int_{\Omega} u_i f_i \quad \text{s.t.} \quad \sum_{i=1}^4 u_i(x) = 1. \quad (12)$$

where $f_i = \frac{\alpha}{2}(s_i - s_0)^2 + |\nabla s_i|^2(\lambda_i^k + \frac{r}{2})$.

An algorithm: Subproblem II

$$\min_{s_i} \int_{\Omega} \frac{h_i}{2} (s_i - s_0)^2 + \frac{g_i}{2} |\nabla s_i|^2 \quad (13)$$

where $h_i = \alpha u_i$ and $g_i = \sigma + (2\lambda_i^k + r)u_i$.

The algorithm

Algorithm for the unsupervised image segmentation model (7) using the four color theorem (with a priori unknown number of regions).

- ▶ Initialize the u_i (random initialization or k-mean). While not converged
 - ▶ s_i^{k+1} computed with Algorithm for s_i
 - ▶ u_i^{k+1} computed with Algorithm for u_i
 - ▶ $\lambda_i^{k+1} = \lambda_i^k + ru_i^{k+1} |\nabla s_i^{k+1}|^2$

Numerical Experiments

Figure: (a) Original image. (b) segmentation into four phase $\{\Omega_i\}_{i=1}^4$ (two distinct regions, central disk and upper right part are merged). (c) segmentation result after segmenting each phase into four sub-phase (this produces sixteen sub-phases $\{\Omega_{i,j}\}_{i,j=1}^4$) and recoloring into four phases (correct result). (d) piecewise constant approximation of (a).

Local minimizers and re-coloring

Two-level recursive algorithm for the unsupervised image segmentation model (2) using the four color theorem (with a priori unknown number of regions).

- ▶ Initialize the u_i (random initialization or k-mean), select the scale parameter α which controls the number of regions.

While not converged.

- ▶ Compute four phases $\{\Omega_i\}_{i=1}^4$ with Algorithm 1
- ▶ Partition each phase $\{\Omega_i\}_{i=1}^4$ into 4 sub-phases $\{\Omega_{i,j}\}_{i,j=1}^4$ with Algorithm 2
- ▶ Recolor the 16 sub-phases into 4 phases

Numerical Experiments

Figure: Comparison between the standard recursive bi-partitioning method and our method: (a) Original image. (b) segmentation after 1st bi-partitioning. (c) segmentation after 2nd/final bi-partitioning (over-segmentation). (d) Our algorithm (correct segmentation).

Numerical Experiments

Figure: Influence of the regularization parameter α . First row is the original image. Second row is the four-color segmentation result. Third row is the piecewise constant approximation of the image. First column $\alpha = 1.5e5/255^2$, second column $\alpha = 3e4/255^2$, third column $\alpha = 1e4/255^2$, fourth column $\alpha = 1e3/255^2$.

Numerical Experiments

Figure: First and fourth rows present the original image. Second and fifth rows show the four-color segmentation result. Third and last rows display the piecewise constant approximation of the image s_0 . Each column present a different value of α , which controls the number of final segmented regions.

Numerical Experiments

Figure: First and fourth rows present the original image. Second and fifth rows show the four-color segmentation result. Third and last rows display the piecewise constant approximation of the image s_0 . Each column present a different value of α , which controls the number of final segmented regions.

Advantages

- ▶ Can automatically determine how many regions.

Advantages

- ▶ Can automatically determine how many regions.
- ▶ Only uses 4 labels.

Advantages

- ▶ Can automatically determine how many regions.
- ▶ Only uses 4 labels.
- ▶ Can take as many constants as is needed for a given regularization parameters.

Advantages

- ▶ Can automatically determine how many regions.
- ▶ Only uses 4 labels.
- ▶ Can take as many constants as is needed for a given regularization parameters.
- ▶ Regularization parameter controls how many regions and constants.

Advantages

- ▶ Can automatically determine how many regions.
- ▶ Only uses 4 labels.
- ▶ Can take as many constants as is needed for a given regularization parameters.
- ▶ Regularization parameter controls how many regions and constants.
- ▶ Fast to compute.

Advantages
